## Millennium Ecosystem Assessment Synthesis Report

Draft 9-edited: 7 March 2005

**Note to reader: This is the penultimate draft of the MA General Synthesis Report. The contents of this draft may change before its final release on March 30. The material in this draft should not be quoted or cited. Information from this draft should be checked against the final draft that will be posted at <http://www.MAweb.org> on March 30, 2005.**

A Report of the Millennium Ecosystem Assessment

**Core Writing Team:** Walter V. Reid, Harold A. Mooney, Angela Cropper, Doris Capistrano, Stephen R. Carpenter, Kanchan Chopra, Partha Dasgupta, Thomas Dietz, Anantha Kumar Duraiappah, Rashid Hassan, Roger Kasperson, Rik Leemans, Robert M. May, Tony (A.J.) McMichael, Prabhu Pingali, Cristián Samper, Robert Scholes, Robert T. Watson, A.H. Zakri, Zhao Shidong, Neville J. Ash, Elena Bennett, Pushpam Kumar, Marcus J. Lee, Ciara Raudsepp-Hearne, Henk Simons, Jillian Thonell, and Monika B. Zurek

**Extended Writing Team:** MA Coordinating Lead Authors, Lead Authors, Contributing Authors, and Sub-Global Coordinators

**Review Editors:** José Sarukhán and Anne Whyte (co-chairs) and MA Board of Review Editors

Offices: IEG India | SCOPE France | UNEP Kenya | UNEP-WCMC UK | WRI & Meridian Institute USA | RIVM Netherlands | WorldFish Center Malaysia

1 **Millennium Ecosystem Assessment Board**

2 The MA Board represents the users of the findings of the MA process.

3

4 **Co-chairs**

5 Robert T. Watson, *World Bank*

6 A.H. Zakri, *United Nations University*

7

8 **Institutional Representatives**

9 Salvatore Arico, *United Nations Educational, Scientific and Cultural Organization*

10 Peter Bridgewater, *Ramsar Convention on Wetlands*

11 Hama Arba Diallo, *United Nations Convention to Combat Desertification*

12 Adel El-Beltagy, *Consultative Group on International Agricultural Research*

13 Max Finlayson, *Ramsar Convention on Wetlands*

14 Colin Galbraith, *Convention on Migratory Species*

15 Erika Harms, *United Nations Foundation*

16 Robert Hepworth, *Convention on Migratory Species*

17 Kerstin Leitner, *World Health Organization*

18 Alfred Oteng-Yeboah, *Convention on Biological Diversity*

19 Christian Prip, *Convention on Biological Diversity*

20 Mario Ramos, *Global Environment Facility*

21 Thomas Rosswall, *International Council for Science*

22 Achim Steiner, *IUCN–The World Conservation Union*

23 Halldor Thorgeirsson, *United Nations Framework Convention on Climate Change*

24 Klaus Töpfer, *United Nations Environment Programme*

25 Jeff Tschirley, *Food and Agricultural Organization of the United Nations*

26 Alvaro Umaña, *United Nations Development Programme*

27 Ricardo Valentini, *United Nations Convention to Combat Desertification*

28 Hamdallah Zedan, *Convention on Biological Diversity*

29

30 **At-large Members**

31 Fernando Almeida

40 Fred Fortier

49 Henry Schacht

32 Phoebe Barnard

41 Mohamed H.A. Hassan

50 Peter Johan Schei

33 Gordana Beltram

42 Jonathan Lash

51 Ismail Serageldin

34 Delmar Blasco

43 Wangari Maathai

52 David Suzuki

35 Antony Burgmans

44 Paul Maro

53 M.S. Swaminathan

36 Esther Camac

45 Harold Mooney (*ex officio*)

54 José Galizia Tundisi

37 Angela Cropper (*ex officio*)

46 Marina Motovilova

55 Axel Wenblad

38 Partha Dasgupta

47 M.K. Prasad

56 Xu Guanhua

39 José Maria Figueres

48 Walter V. Reid

57 Muhammad Yunus

8 **MA Director**

9 Walter V. Reid, Millennium Ecosystem Assessment

10

11 **Millennium Ecosystem Assessment Secretariat Support Organizations**

12 The United Nations Environment Programme coordinates the Millennium Ecosystem Assessment  
13 Secretariat, which is based at the following partner institutions:

14 Food and Agricultural Organization of the United Nations, Italy

15 Institute of Economic Growth, India

16 International Maize and Wheat Improvement Center, Mexico (*until 2004*)

17 Meridian Institute, United States

18 National Institute of Public Health and the Environment, Netherlands (*until mid-2004*)

19 Scientific Committee on Problems of the Environment, France

20 UNEP-World Conservation Monitoring Centre, United Kingdom

21 University of Pretoria, South Africa

22 University of Wisconsin, United States

23 World Resources Institute, United States

24 WorldFish Center, Malaysia

# 1 Foreword

2 The Millennium Ecosystem Assessment was called for by United Nations Secretary-General  
3 Kofi Annan in 2000 in his report to the UN General Assembly, *We the Peoples: The Role of*  
4 *the United Nations in the 21<sup>st</sup> Century*. Governments subsequently supported the  
5 establishment of the assessment through decisions taken by three international conventions,  
6 and the MA was initiated in 2001. The MA was conducted under the auspices of the United  
7 Nations, with the secretariat coordinated by the United Nations Environment Programme, and  
8 it was governed by a multistakeholder board involving international institutions and  
9 representatives of governments, business, NGOs, and indigenous peoples. The objective of  
10 the MA was to assess the consequences of ecosystem change for human well-being and to  
11 establish the scientific basis for actions needed to enhance the conservation and sustainable  
12 use of ecosystems and their contributions to human well-being.

13 This report presents a synthesis and integration of the findings of the four MA Working  
14 Groups (Condition and Trends, Scenarios, Responses, and Sub-Global Assessments). It does  
15 not, however, provide a comprehensive summary of each Working Group report, and readers  
16 are encouraged to also review the findings of these separately. This synthesis is organized  
17 around the core questions originally posed to the assessment: How have ecosystems and their  
18 services changed? What has caused these changes? How have these changes affected human  
19 well-being? How might ecosystems change in the future and what are the implications for  
20 human well-being? And what options exist to enhance the conservation of ecosystems and  
21 their contribution to human well-being?

22 This assessment would not have been possible without the extraordinary commitment of the  
23 approximately 1,360 experts worldwide who contributed their knowledge, creativity, time,  
24 and enthusiasm to this process. We would like to express our gratitude to the members of the  
25 MA Assessment Panel, Coordinating Lead Authors, Lead Authors, Contributing Authors,  
26 Board of Review Editors, and Expert Reviewers who contributed to this process, and we wish  
27 to acknowledge the in-kind support of their institutions, which enabled their participation.  
28 (The list of reviewers is available at [www.MAweb.org](http://www.MAweb.org).)

29 We would like to thank the host organizations of the MA Technical Support Units—  
30 WorldFish Center (Malaysia); UNEP-World Conservation Monitoring Centre (United  
31 Kingdom); Institute of Economic Growth (India); National Institute of Public Health and the  
32 Environment (Netherlands); University of Pretoria (South Africa), U.N. Food and Agriculture  
33 Organization; World Resources Institute, Meridian Institute, and Center for Limnology of the  
34 University of Wisconsin (all in the United States); Scientific Committee on Problems of the  
35 Environment (France); and International Maize and Wheat Improvement Center (Mexico)—  
36 for the support they provided to the process.

37 We thank the MA secretariat staff, interns, and volunteers, the administrative staff of the host  
38 organizations, and colleagues in other organizations who were instrumental in facilitating the  
39 process: Isabelle Alegre, Adlai Amor, Neville Ash, Elena Bennett, Hyacinth Billings, Cecilia  
40 Blasco, Delmar Blasco, Emmanuelle Bournay, Herbert Caudill, Chan Wai Leng, Lina  
41 Cimarrusti, Emily Cooper, Dalène du Plessis, John Ehrmann, Keisha-Maria Garcia, Habiba  
42 Gitay, Helen Gray, Lori Han, Sherry Heileman, Toshie Honda, Francisco Ingouville,  
43 Christine Jalleh, Humphrey Kagunda, Nicole Khi, Brygida Kubiak, Pushpam Kumar, Marcus  
44 Lee, Liz Levitt, Belinda Lim, Nicolas Lucas, Christian Marx, Mampiti Matete, Tasha  
45 Merican, Stephanie Moore, John Mukoza, Arivudai Nambi, Laurie Neville, Rosemarie

1 Philips, Veronique Plocq Fichelet, Maggie Powell, Meenakshi Rathore, Ciara Raudsepp-  
2 Hearne, Carolina Katz Reid, Walter Reid, Liana Reilly, Philippe Rekacewicz, Carol Rosen,  
3 Mariana Sanchez Abregu, Anne Schram, Tang Siang Nee, Henk Simons, Linda Starke, Sara  
4 Suriani, Darrell Taylor, Valerie Thompson, Jillian Thonell, Tutti Tischler, Elsie Velez  
5 Whited, Elizabeth Wilson, Mark Zimsky, and Monika Zurek.

6 We thank the members of the MA Board for the guidance and oversight they provided to this  
7 process. In addition to the current Board members (listed earlier), the contributions of past  
8 members of the MA Board were instrumental in shaping the MA focus and process and these  
9 individuals include Philbert Brown, Gisbert Glaser, He Changchui, Richard Helmer, Yolanda  
10 Kakabadse, Yoriko Kawaguchi, Ann Kern, Roberto Lenton, Hubert Markl, Arnulf Müller-  
11 Helbrecht, Corinne Lepage, Alfred Oteng-Yeboah, Seema Paul, Susan Pineda Mercado, Jan  
12 Plesnik, Peter Raven, Cristián Samper, Ola Smith, Dennis Tirpak, and Meryl Williams. We  
13 wish to also thank the members of the Exploratory Steering Committee that designed the MA  
14 project in 1999–2000. This group included a number of the current and past Board members,  
15 as well as Edward Ayensu, Mark Collins, Andrew Dearing, Louise Fresco, Madhav Gadgil,  
16 Habiba Gitay, Zuzana Guziova, Calestous Juma, John Krebs, Jane Lubchenco, Jeffrey  
17 McNeely, Ndegwa Ndiang'ui, Janos Pasztor, Prabhu L. Pingali, Per Pinstrup-Andersen, and  
18 José Sarukhán. And we would like to acknowledge the support and guidance provided by the  
19 secretariats and the scientific and technical bodies of the Convention on Biological Diversity,  
20 the Ramsar Convention on Wetlands, the Convention to Combat Desertification, and the  
21 Convention on Migratory Species, which have helped to define the focus of the MA and of  
22 this report. We are grateful to two members of the Board of Review Editors, Gordon Orians  
23 and Richard Norgaard, who played a particularly important role during the review and  
24 revision of this synthesis report. And, we would like to thank Ian Noble and Mingsarn  
25 Kaosa-ard for their contributions as members of the Assessment Panel during 2002.

26 We also want to acknowledge the support of a large number of nongovernmental  
27 organizations and networks around the world that have assisted in outreach efforts:  
28 Alexandria University, Argentine Business Council for Sustainable Development, Asociación  
29 Ixacavaa (Costa Rica), Arab Media Forum for Environment and Development, Brazilian  
30 Business Council on Sustainable Development, Charles University (Czech Republic),  
31 Chinese Academy of Sciences, European Environmental Agency, European Union of Science  
32 Journalists' Associations, EIS-Africa (Burkina Faso), Forest Institute of the State of São  
33 Paulo, Foro Ecológico (Peru), Fridtjof Nansen Institute (Norway), Fundación Natura  
34 (Ecuador), Global Development Learning Network, Indonesian Biodiversity Foundation,  
35 Institute for Biodiversity Conservation and Research–Academy of Sciences of Bolivia,  
36 International Alliance of Indigenous Peoples of the Tropical Forests, IUCN office in  
37 Uzbekistan, IUCN Regional Offices for West Africa and South America, Permanent Inter-  
38 States Committee for Drought Control in the Sahel, Peruvian Society of Environmental Law,  
39 Probioandes (Peru), Professional Council of Environmental Analysts of Argentina, Regional  
40 Center AGRHYMET (Niger), Regional Environmental Centre for Central Asia, Resources  
41 and Research for Sustainable Development (Chile), Royal Society (United Kingdom),  
42 Stockholm University, Suez Canal University, Terra Nuova (Nicaragua), The Nature  
43 Conservancy (United States), United Nations University, University of Chile, University of  
44 the Philippines, World Assembly of Youth, World Business Council for Sustainable  
45 Development, WWF-Brazil, WWF-Italy, and WWF-US.  
46

1 We are extremely grateful to the donors that provided major financial support for the MA and  
2 the MA Sub-global Assessments: Global Environment Facility; United Nations Foundation;  
3 David and Lucile Packard Foundation; World Bank; Consultative Group on International  
4 Agricultural Research; United Nations Environment Programme; Government of China;  
5 Government of Norway; Kingdom of Saudi Arabia; Swedish International Biodiversity  
6 Programme. We also thank other organizations that provided financial support: Asia Pacific  
7 Network for Global Change Research; Association of Caribbean States; British High  
8 Commission, Trinidad & Tobago; Caixa Geral de Depósitos, Portugal; Canadian  
9 International Development Agency; Christensen Fund; Cropper Foundation, Environmental  
10 Management Authority of Trinidad and Tobago; Ford Foundation; Government of India;  
11 International Council for Science; International Development Research Centre; Island  
12 Resources Foundation; Japan Ministry of Environment; Laguna Lake Development  
13 Authority; Philippine Department of Environment and Natural Resources; Rockefeller  
14 Foundation; U.N. Educational, Scientific and Cultural Organization; UNEP Division of Early  
15 Warning and Assessment; United Kingdom Department for Environment, Food and Rural  
16 Affairs; United States National Aeronautic and Space Administration; and, Universidade de  
17 Coimbra, Portugal. Generous in-kind support has been provided by many other institutions  
18 (a full list is available at [www.MAweb.org](http://www.MAweb.org)). The work to establish and design the MA was  
19 supported by grants from The Avina Group, The David and Lucile Packard Foundation,  
20 Global Environment Facility, Government of Norway, Swedish International Development  
21 Cooperation Authority, Summit Foundation, UNDP, UNEP, the United Nations Foundation,  
22 United States Agency for International Development, Wallace Global Fund, and World Bank.

23 Finally, we would particularly like to thank Angela Cropper and Harold Mooney, the co-  
24 chairs of the MA Assessment Panel, José Sarukhán and Anne Whyte, the co-chairs of the MA  
25 Review Board, and Walter Reid, the MA Director, for their skillful leadership of the  
26 assessment and review processes.

38 Executive Director, United Nations Environment Programme  
39 Director General, United Nations Office in Nairobi

# 1 Preface

2 The Millennium Ecosystem Assessment was carried out between 2001 and 2005 to assess the  
3 consequences of ecosystem change for human well-being and to establish the scientific basis  
4 for actions needed to enhance the conservation and sustainable use of ecosystems and their  
5 contributions to human well-being. The MA responds to government requests for  
6 information received through four international conventions—the Convention on Biological  
7 Diversity, the United Nations Convention to Combat Desertification, the Ramsar Convention  
8 on Wetlands, and the Convention on Migratory Species—and is designed to also meet needs  
9 of other stakeholders, including the business community, the health sector, nongovernmental  
10 organizations, and indigenous peoples.

11 The assessment focuses on the linkages between ecosystems and human well-being and, in  
12 particular, on “ecosystem services.” An ecosystem is a dynamic complex of plant, animal,  
13 and microorganism communities and the nonliving environment interacting as a functional  
14 unit. The MA deals with the full range of ecosystems—from those relatively undisturbed,  
15 such as natural forests, to landscapes with mixed patterns of human use, to ecosystems  
16 intensively managed and modified by humans, such as agricultural land and urban areas.  
17 Ecosystem services are the benefits people obtain from ecosystems. These include  
18 *provisioning services* such as food, water, timber, and fiber; *regulating services* that affect  
19 climate, floods, disease, wastes, and water quality; *cultural services* that provide recreational,  
20 aesthetic, and spiritual benefits; and *supporting services* such as soil formation,  
21 photosynthesis, and nutrient cycling. (See Figure A.) The human species, while buffered  
22 against environmental changes by culture and technology, is ultimately fully dependent on  
23 the flow of ecosystem services.

24 The MA examines how changes in ecosystem services influence human well-being. Human  
25 well-being is assumed to have multiple constituents, including the *basic material for a good*  
26 *life*, such as secure and adequate livelihoods, enough food at all times, shelter, clothing, and  
27 access to goods; *health*, including feeling well and having a healthy physical environment,  
28 such as clean air and access to clean water; *good social relations*, including social cohesion,  
29 mutual respect, and the ability to help others and provide for children; *security*, including  
30 secure access to natural and other resources, personal safety, and security from natural and  
31 human-made disasters; and *freedom of choice and action*, including the opportunity to  
32 achieve what an individual values doing and being. Freedom of choice and action is  
33 influenced by other constituents of well-being (as well as by other factors, notably education)  
34 and is also a precondition for achieving other components of well-being, particularly with  
35 respect to equity and fairness.

36 The conceptual framework for the MA assumes that people are integral parts of ecosystems  
37 and that a dynamic interaction exists between them and other parts of ecosystems, with the  
38 changing human condition driving, both directly and indirectly, changes in ecosystems and  
39 thereby causing changes in human well-being. (See Figure B.) At the same time, social,  
40 economic, and cultural factors unrelated to ecosystems alter the human condition, and many  
41 natural forces influence ecosystems. Although the MA emphasizes the linkages between  
42 ecosystems and human well-being, it recognizes that the actions people take that influence  
43 ecosystems result not just from concern about human well-being but also from considerations  
44 of the intrinsic value of species and ecosystems. Intrinsic value is the value of something in  
45 and for itself, irrespective of its utility for someone else.

1 The Millennium Ecosystem Assessment synthesizes information from the scientific literature  
2 and relevant peer-reviewed datasets and models. It incorporates knowledge held by the  
3 private sector, practitioners, local communities, and indigenous peoples. The MA did not  
4 aim to generate new primary knowledge, but instead sought to add value to existing  
5 information by collating, evaluating, summarizing, interpreting, and communicating it in a  
6 useful form. Assessments like this one apply the judgment of experts to existing knowledge  
7 to provide scientifically credible answers to policy-relevant questions. The focus on policy-  
8 relevant questions and the explicit use of expert judgment distinguish this type of assessment  
9 from a scientific review.

10 Five overarching questions, along with more detailed lists of user needs developed through  
11 discussions with stakeholders or provided by governments through international conventions,  
12 guided the issues that were assessed:

- 13     ▪ What are the current condition and trends of ecosystems and human well-being?
- 14     ▪ What are the plausible future changes in ecosystems and their ecosystem services and  
15     the consequent changes in human well-being?
- 16     ▪ What can be done to enhance well-being and conserve ecosystems? What are the  
17     strengths and weaknesses of response options that can be considered to realize or  
18     avoid specific futures?
- 19     ▪ What are the key uncertainties that hinder effective decision-making concerning  
20     ecosystems?
- 21     ▪ What tools and methodologies developed and used in the MA can strengthen capacity  
22     to assess ecosystems, the services they provide, their impacts on human well-being,  
23     and the strengths and weaknesses of response options?

24 The MA was conducted as a multiscale assessment, with interlinked assessments undertaken  
25 at local, watershed, national, regional, and global scales. A global ecosystem assessment  
26 cannot easily meet the needs of decision-makers at national and sub-national scales because  
27 the management of any particular ecosystem must be tailored to the particular characteristics  
28 of that ecosystem and to the demands placed on it. However, an assessment focused only on  
29 a particular ecosystem or particular nation is insufficient because some processes are global  
30 and because local goods, services, matter, and energy are often transferred across regions.  
31 Each of the component assessments was guided by the MA conceptual framework and  
32 benefited from the presence of assessments undertaken at larger and smaller scales. The sub-  
33 global assessments were not intended to serve as representative samples of all ecosystems;  
34 rather, they were to meet the needs of decision-makers at the scales at which they were  
35 undertaken.

36 The work of the MA was conducted through four working groups, each of which prepared a  
37 report of its findings. At the global scale, the Condition and Trends Working Group assessed  
38 the state of knowledge on ecosystems, drivers of ecosystem change, ecosystem services, and  
39 associated human well-being around the year 2000. The assessment aimed to be  
40 comprehensive with regard to ecosystem services, but its coverage is not exhaustive. The  
41 Scenarios Working Group considered the possible evolution of ecosystem services during the  
42 twenty-first century by developing four global scenarios exploring plausible future changes in  
43 drivers, ecosystems, ecosystem services, and human well-being. The Responses Working  
44 Group examined the strengths and weaknesses of various response options that have been  
45 used to manage ecosystem services and identified promising opportunities for improving  
46 human well-being while conserving ecosystems. The report of the Sub-global Working

1 Group contains a synthesis of the key findings of the MA sub-global assessments. The first  
2 product of the MA—*Ecosystems and Human Well-being: A Framework for Assessment*,  
3 published in 2003—outlined the focus, conceptual basis, and methods used in the MA.

4 Approximately 1,360 experts from 95 countries were involved as authors of the assessment  
5 reports, as participants in the sub-global assessments, or as members of the Board of Review  
6 Editors. (See Appendix C for the list of authors and review editors.) The latter group, which  
7 involved 80 experts, oversaw the scientific review of the MA reports by governments and  
8 experts and ensured that all review comments were appropriately addressed by the authors.  
9 All MA findings underwent two rounds of expert and governmental review. Review  
10 comments were received from approximately 850 individuals (of which roughly 250 were  
11 submitted by authors of other chapters in the MA), although in a number of cases  
12 (particularly in the case of governments and MA-affiliated scientific organizations), people  
13 submitted collated comments that had been prepared by a number of reviewers in their  
14 governments or institutions.

15 The MA was guided by a Board that included representatives of five international  
16 conventions, five U.N. agencies, international scientific organizations, and leaders from the  
17 private sector, nongovernmental organizations, and indigenous groups. A 13-member  
18 Assessment Panel of leading social and natural scientists oversaw the technical work of the  
19 assessment, supported by a secretariat with offices in Europe, North America, South  
20 America, Asia, and Africa and coordinated by the United Nations Environment Programme.

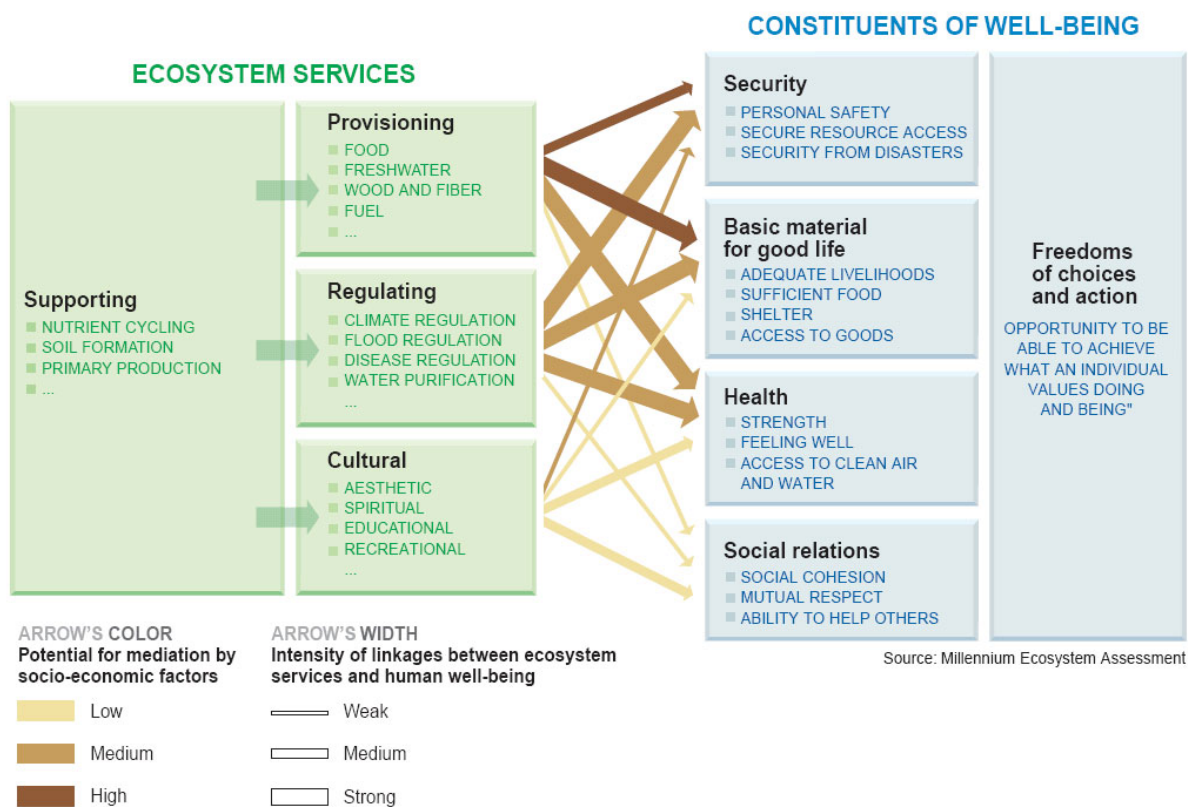

21 The MA is intended to be used:

- 22     ▪ to identify priorities for action;
- 23     ▪ as a benchmark for future assessments;
- 24     ▪ as a framework and source of tools for assessment, planning, and management;
- 25     ▪ to gain foresight concerning the consequences of decisions affecting ecosystems;
- 26     ▪ to identify response options to achieve human development and sustainability goals;
- 27     ▪ to help build individual and institutional capacity to undertake integrated ecosystem  
28         assessments and act on the findings; and
- 29     ▪ to guide future research.

30 Because of the broad scope of the MA and the complexity of the interactions between social  
31 and natural systems, it proved to be difficult to provide definitive information for some of the  
32 issues addressed in the MA. Relatively few ecosystem services have been the focus of  
33 research and monitoring and, as a consequence, research findings and data are often  
34 inadequate for a detailed global assessment. Moreover, the data and information that are  
35 available are generally related to either the characteristics of the ecological system or the  
36 characteristics of the social system, not to the all-important interactions between these  
37 systems. Finally, the scientific and assessment tools and models available to undertake a  
38 cross-scale integrated assessment and to project future changes in ecosystem services are only  
39 now being developed. Despite these challenges, the MA was able to provide considerable  
40 information relevant to most of the focal questions. And by identifying gaps in data and  
41 information that prevent policy-relevant questions from being answered, the assessment can  
42 help to guide research and monitoring that may allow those questions to be answered in  
43 future assessments.

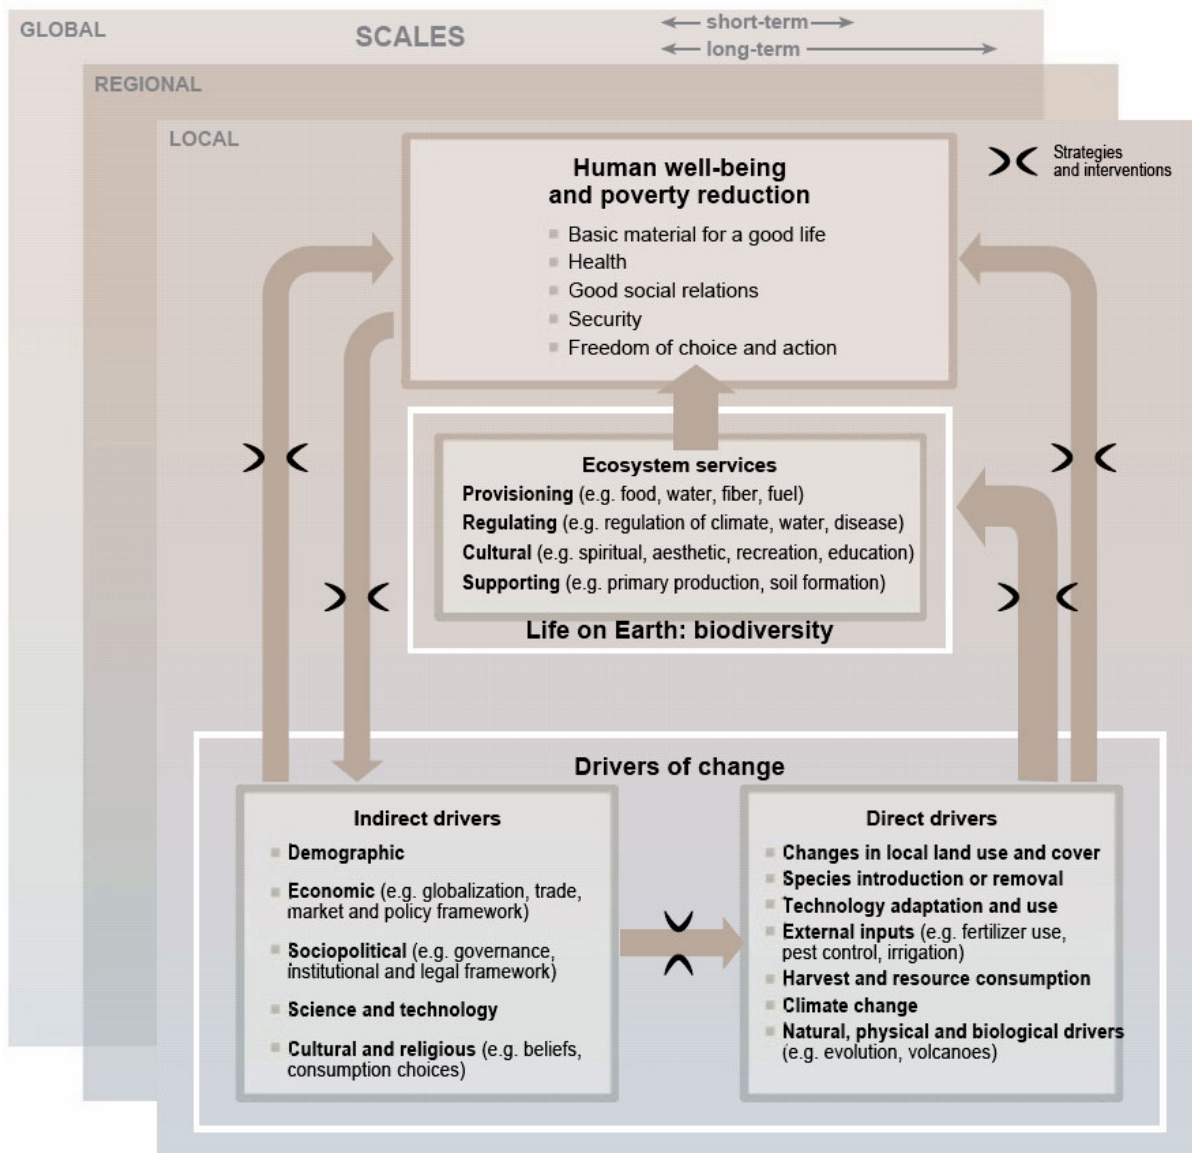

1 **Figure A. Linkages between Ecosystem Services and Human Well-being.** This figure  
 2 depicts the strength of linkages between categories of ecosystem services and components of  
 3 human well-being that are commonly encountered, and includes indications of the extent to  
 4 which it is possible for socioeconomic factors to mediate the linkage. (For example, if it is  
 5 possible to purchase a substitute for a degraded ecosystem service, then there is a high  
 6 potential for mediation.) The strength of the linkages and the potential for mediation differ in  
 7 different ecosystems and regions. In addition to the influence of ecosystem services on  
 8 human well-being depicted here, other factors—including other environmental factors as well  
 9 as economic, social, technological, and cultural factors—influence human well-being, and  
 10 ecosystems are in turn affected by changes in human well-being. (See Figure B.)

11

12

1 **Figure B. Framework of Interactions between Biodiversity, Ecosystem Services,**  
 2 **Human Well-being, and Drivers of Change.** Changes in drivers that indirectly affect  
 3 biodiversity, such as population, technology, and lifestyle (lower left corner of figure), can  
 4 lead to changes in drivers directly affecting biodiversity, such as the catch of fish or the  
 5 application of fertilizers (lower right corner). These result in changes to ecosystems and the  
 6 services they provide (center), thereby affecting human well-being. These interactions can  
 7 take place at more than one scale and can cross scales. For example, an international demand  
 8 for timber may lead to a regional loss of forest cover, which increases flood magnitude along  
 9 a local stretch of a river. Similarly, the interactions can take place across different time scales.  
 10 Different strategies and interventions can be applied at many points in this framework to  
 11 enhance human well-being and conserve ecosystems.

12

# 1 **Reader's Guide**

2 This report presents a synthesis and integration of the findings of the four MA Working  
3 Groups along with more detailed findings for selected ecosystem services concerning  
4 condition and trends and scenarios (see Appendix A) and response options (see Appendix B).  
5 Five additional synthesis reports were prepared for ease of use by specific audiences: CBD  
6 (biodiversity), UNCCD (desertification), Ramsar Convention (wetlands), business, and the  
7 health sector. Each MA sub-global assessment will also produce additional reports to meet  
8 the needs of its own audience. The full technical assessment reports of the four MA Working  
9 Groups will be published in mid-2005 by Island Press. All printed materials of the  
10 assessment, along with core data and a glossary of terminology used in the technical reports,  
11 will be available on the Internet at [www.MAweb.org](http://www.MAweb.org). Appendix D lists the acronyms and  
12 abbreviations used in this report.

13 References that appear in parentheses in the body of this synthesis report are to the  
14 underlying chapters in the full technical assessment reports of each Working Group. (A list of  
15 the assessment report chapters is provided in Appendix E.) Bracketed references within the  
16 Summary for Decision-makers are to the chapters of this full synthesis report, where  
17 additional information on each topic can be found.

18 In this report, the following words have been used where appropriate to indicate judgmental  
19 estimates of certainty, based on the collective judgment of the authors, using the  
20 observational evidence, modeling results, and theory that they have examined: very certain  
21 (98% or greater probability), high certainty (85–98% probability), medium certainty (65–85%  
22 probability), low certainty (52–65% probability), and very uncertain (50–52% probability). In  
23 other instances, a qualitative scale to gauge the level of scientific understanding is used: well  
24 established, established but incomplete, competing explanations, and speculative. Each time  
25 these terms are used they appear in italics.

26 Throughout this report, dollar signs indicate U.S. dollars and tons means metric tons.  
27

# 1 Summary for Decision-makers

2 Everyone in the world depends completely on Earth’s ecosystems and the services they  
3 provide, such as food, water, disease management, climate regulation, spiritual fulfillment,  
4 and aesthetic enjoyment. Over the past 50 years, humans have changed these ecosystems  
5 more rapidly and extensively than in any comparable period of time in human history, largely  
6 to meet rapidly growing demands for food, fresh water, timber, fiber, and fuel. This  
7 transformation of the planet has contributed to substantial net gains in human well-being and  
8 economic development. But all regions and groups of people have not benefited from this  
9 process—in fact, many have been harmed. Moreover, the full costs associated with these  
10 gains are only now becoming apparent.

11 Three major problems associated with our management of the world’s ecosystems are already  
12 causing significant harm to people and will substantially diminish the long-term benefits we  
13 obtain from ecosystems:

- 14     ▪ First, approximately 60% (15 out of 24) of the ecosystem services examined during  
15     the Millennium Ecosystem Assessment are being degraded or used unsustainably,  
16     including fresh water, capture fisheries, air and water purification, and the regulation  
17     of regional and local climate, natural hazards, and pests. The full costs of the loss and  
18     degradation of these ecosystem services are difficult to measure, but the available  
19     evidence indicates that they are substantial and growing. Many ecosystem services  
20     have been degraded as a consequence of actions taken to increase the supply of other  
21     services, such as food. These trade-offs often shift the costs of degradation from one  
22     group of people to another or defer costs to future generations.
- 23     ▪ Second, there is established but incomplete evidence that changes being made in  
24     ecosystems are increasing the likelihood of nonlinear (that is, stepped) and potentially  
25     abrupt changes in ecosystems that have important consequences for human well-being.

## Four Main Findings

Over the past 50 years, humans have changed ecosystems more rapidly and extensively than in any comparable period of time in human history, largely to meet rapidly growing demands for food, fresh water, timber, fiber and fuel. This has resulted in a substantial and largely irreversible loss in the diversity of life on Earth.

The changes that have been made to ecosystems have contributed to substantial net gains in human well-being and economic development, but these gains have been achieved at growing costs in the form of the degradation of many ecosystem services, increased risks of nonlinear changes, and the exacerbation of poverty for some groups of people. These problems will substantially diminish the benefits that future generations obtain from ecosystems.

The degradation of ecosystem services could grow significantly worse during the first half of this century and is a barrier to achieving the Millennium Development Goals.

The challenge of reversing the degradation of ecosystems while meeting increasing demands for their services can be met under some scenarios involving significant policy and institutional changes, but these changes are large and not currently under way. Many options exist to conserve or enhance specific ecosystem services in ways that reduce negative trade-offs or that provide positive synergies with other ecosystem services.

1 Examples of such changes include disease emergence, abrupt alterations in water  
2 quality, the creation of “dead zones” in coastal waters, the collapse of fisheries, and  
3 shifts in regional climate.

- 4 ▪ Third, the degradation of ecosystem services is harming many of the world’s poorest  
5 people, which is contributing to growing inequities and disparities across groups of  
6 people and is sometimes the principal factor causing poverty. This is not to say that  
7 ecosystem changes such as increased food production have not also helped to lift  
8 hundreds of millions of people out of poverty, but these changes have harmed many  
9 other individuals and communities, and their plight has been largely overlooked. In  
10 some regions, such as sub-Saharan Africa, the condition and management of  
11 ecosystem services is a dominant factor influencing prospects for reducing poverty.

12 The ongoing degradation of ecosystem services is a significant barrier to achieving the  
13 Millennium Development Goals agreed to by the international community in September 2000.  
14 And the harmful consequences of this degradation could grow significantly worse in the next  
15 50 years. Already, the regions facing the greatest challenges in achieving the MDGs coincide  
16 with those facing significant problems of ecosystem degradation: sub-Saharan Africa, Central  
17 Asia, and parts of South and Southeast Asia, as well as some regions in Latin America. The  
18 consumption of ecosystem services, which is already unsustainable in many cases, will  
19 continue to grow as a consequence of a likely three- to sixfold increase in global GDP by  
20 2050 even while global population growth is expected to slow and level off in mid-century.  
21 Most of the important direct drivers of ecosystem change are unlikely to diminish in the first  
22 half of the century and two drivers—climate change and excessive nutrient loading—will  
23 become more severe. Any progress achieved in addressing the MDGs of poverty and hunger  
24 eradication, improved health, and environmental protection is unlikely to be sustained if most  
25 of the ecosystem services on which humanity relies continue to be degraded.

26 There is no simple fix to these problems since they arise from the interaction of many  
27 recognized challenges, including climate change, biodiversity loss, and land degradation,  
28 each of which is complex to address in its own right. Nevertheless, there is tremendous scope  
29 for action that could lessen the severity of these problems in the coming decades. Indeed,  
30 three of four detailed scenarios examined by the MA show that significant changes in policy  
31 can mitigate many of the negative consequences of growing pressures on ecosystems. But the  
32 changes required are substantial and are not currently under way.

33 An effective set of responses to ensure the sustainable management of ecosystems requires  
34 changes in institutions and governance, economic policies and incentives, social and behavior  
35 factors, technology, and knowledge. Actions such as the integration of ecosystem  
36 management goals in other sectors, increased transparency and accountability of government  
37 and private-sector performance in ecosystem management, elimination of perverse subsidies,  
38 greater use of economic instruments and market-based approaches, empowerment of groups  
39 dependent on ecosystem services or affected by their degradation, promotion of technologies  
40 enabling increased crop yields without harmful environmental impacts, ecosystem restoration,  
41 and the incorporation of nonmarket values of ecosystems in management decisions all could  
42 substantially lessen the severity of these problems in the next several decades.

43 The remainder of this *Summary for Decision-makers* presents the four major findings of the  
44 Millennium Ecosystem Assessment on the problems to be addressed and the actions needed  
45 to enhance the conservation and sustainable use of ecosystems.

**Finding #1: Over the past 50 years, humans have changed ecosystems more rapidly and extensively than in any comparable period of time in human history, largely to meet rapidly growing demands for food, fresh water, timber, fiber and fuel. This has resulted in a substantial and largely irreversible loss in the diversity of life on Earth.**

**The structure and functioning of the world's ecosystems changed more rapidly in the second half of the twentieth century than at any time in human history. [1]**

- More land was converted to cropland since 1945 than in the eighteenth and nineteenth centuries combined. Cultivated systems (areas where at least 30% of the landscape is in croplands, shifting cultivation, confined livestock production, or freshwater aquaculture) now cover one quarter of Earth's terrestrial surface. (See Figure 1.) Areas of rapid change in forest land cover and land degradation are shown in Figure 2.
- Approximately one quarter of the world's coral reefs were badly degraded or destroyed in the last several decades of the twentieth century, and approximately 35% of mangrove area has been lost in this time (in countries for which sufficient data exist, which encompass about half of the area of mangroves).
- The amount of water impounded behind dams quadrupled since 1960, and three to six times as much water is held in reservoirs as in natural rivers. Water withdrawals from rivers and lakes doubled since 1960; most water use (70% worldwide) is for agriculture.
- Since 1960, flows of reactive (biologically available) nitrogen in terrestrial ecosystems have doubled, and flows of phosphorus have tripled. More than half of all the synthetic nitrogen fertilizer, which was first manufactured in 1913, ever used on the planet has been used since 1985.
- Since 1750, the atmospheric concentration of carbon dioxide has increased by about 32% (from about 280 to 376 parts per million in 2003), primarily due to the combustion of fossil fuels and land use changes. Approximately 60% of that increase (60 parts per million) has taken place since 1959.

**Humans are fundamentally, and to a significant extent irreversibly, changing the diversity of life on Earth, and most of these changes represent a loss of biodiversity. [1]**

- More than two thirds of the area of 2 of the world's 14 major terrestrial biomes (temperate grasslands and Mediterranean forests) and more than half of the area of four other biomes (tropical dry forests, temperate broadleaf forests, tropical grassland, and flooded grasslands) had been converted by 1990, primarily to agriculture. (See Figure 3.)
- Across a range of taxonomic groups, either the population size or range or both of the majority of species is currently declining.
- The distribution of species on Earth is becoming more homogenous; in other words, the set of species in any one region of the world are becoming more similar to other regions primarily as a result of the massive movement of species associated with increased travel and shipping.
- The number of species on the planet is declining. Over the past few hundred years, humans have increased the species extinction rate by between 50 and 1,000 times over background rates typical over the planet's history. (See Figure 4.) Some 10–30% of mammal, bird, and amphibian species are currently threatened with extinction.
- Genetic diversity has declined globally, particularly among cultivated species.

1 **Most changes to ecosystems have been made to meet a dramatic growth in the demand**  
2 **for food, water, timber, fiber, and fuel.** [2] Some ecosystem changes have been the  
3 inadvertent result of activities unrelated to the use of ecosystem services, such as the  
4 construction of roads, ports, and cities and the discharge of pollutants. But most ecosystem  
5 changes were the direct or indirect result of changes made to meet growing demands for  
6 ecosystem services, and in particular growing demands for food, water, timber, fiber, and fuel  
7 (fuelwood and hydropower). Between 1960 and 2000, the demand for ecosystem services  
8 grew significantly as world population doubled to 6 billion people and the global economy  
9 increased more than sixfold. To meet this demand, food production increased by roughly  
10 two-and-a-half times, water use doubled, wood harvests for pulp and paper production  
11 tripled, installed hydropower capacity doubled, and timber production increased by more than  
12 half.

13 The growing demand for these ecosystem services was met both by consuming an increasing  
14 fraction of the available supply (for example, diverting more water for irrigation or capturing  
15 more fish from the sea) and by raising the production of some services, such as crops and  
16 livestock. The latter has been accomplished through the use of new technologies (such as  
17 new crop varieties, fertilization, and irrigation) as well as through increasing the area  
18 managed for the services in the case of crop and livestock production and aquaculture.

19 **Finding #2: The changes that have been made to ecosystems have contributed to**  
20 **substantial net gains in human well-being and economic development, but these gains**  
21 **have been achieved at growing costs in the form of the degradation of many ecosystem**  
22 **services, increased risks of nonlinear changes, and the exacerbation of poverty for some**  
23 **groups of people. These problems will substantially diminish the benefits that future**  
24 **generations obtain from ecosystems.**

25 **In the aggregate, and for most countries, changes made to the world's ecosystems in**  
26 **recent decades have provided substantial benefits for human well-being and national**  
27 **development.** [3] Many of the most significant changes to ecosystems have been essential to  
28 meet growing needs for food and water; these changes have helped reduce the proportion of  
29 malnourished people and improved human health. Agriculture, including fisheries, and  
30 forestry have been the mainstay of strategies for the development of countries for centuries,  
31 providing revenues that have enabled investments in industrialization and poverty alleviation.  
32 Although the value of food production in 2000 was only about 3% of global gross domestic  
33 product, the agricultural labor force accounts for approximately 22% of the world's  
34 population, half the world's total labor force, and 24% of GDP in countries with a per capita  
35 GNP less than \$765 (the low-income developing countries, as defined by the World Bank).

36 **These gains have been achieved, however, at growing costs in the form of the**  
37 **degradation of many ecosystem services, increased risks of large nonlinear changes in**  
38 **ecosystems, and the exacerbation of poverty for some people and a contribution to**  
39 **growing inequities and disparities across groups of people.**

#### 40 *Degradation and Unsustainable Use of Ecosystem Services*

41 **Approximately 60% (15 out of 24) of the ecosystem services evaluated in this assessment**  
42 **(including 70% of regulating and cultural services) are being degraded or used**  
43 **unsustainably.** [2] (See Table 1.) Ecosystem services that have been degraded over the past  
44 50 years include capture fisheries, water supply, waste treatment and detoxification, water  
45 purification, natural hazard protection, regulation of air quality, regulation of regional and

1 local climate, regulation of erosion, spiritual fulfillment, and aesthetic enjoyment. The use of  
2 two ecosystem services—capture fisheries and fresh water—is now well beyond levels that  
3 can be sustained even at current demands, much less future ones. At least one quarter of  
4 important commercial fish stocks are overharvested (*high certainty*). (See Figures 5, 6, and  
5 7.) From 5% to possibly 25% of global freshwater use exceeds long-term accessible supplies  
6 and is now met either through engineered water transfers or overdraft of groundwater  
7 supplies (*low to medium certainty*). Some 15–35% of irrigation withdrawals exceed supply  
8 rates and are therefore unsustainable (*low to medium certainty*). While 15 services have been  
9 degraded, only 4 have been enhanced in the past 50 years, three of which involve food  
10 production: crops, livestock, and aquaculture. Terrestrial ecosystems were on average a net  
11 source of CO<sub>2</sub> emissions during the nineteenth and early twentieth centuries, but became a  
12 net sink around the middle of the last century, and thus in the last 50 years the role of  
13 ecosystems in regulating global climate through carbon sequestration has also been enhanced.

14 **Actions to increase one ecosystem service often cause the degradation of other services.**  
15 [2, 6] For example, because actions to increase food production typically involve increased  
16 use of water and fertilizers or expansion of the area of cultivated land, these same actions  
17 often degrade other ecosystem services, including reducing the availability of water for other  
18 uses, degrading water quality, reducing biodiversity, and decreasing forest cover (which in  
19 turn may lead to the loss of forest products and the release of greenhouse gasses). Similarly,  
20 the conversion of forest to agriculture can significantly change the frequency and magnitude  
21 of floods, although the nature of this impact depends on the characteristics of the local  
22 ecosystem and the type of land cover change.

23 **The degradation of ecosystem services often causes significant harm to human well-**  
24 **being.** [3, 6] The information available to assess the consequences of changes in ecosystem  
25 services for human well-being is relatively limited. Many ecosystem services have not been  
26 monitored, and it is also difficult to estimate the influence of changes in ecosystem services  
27 relative to other social, cultural, and economic factors that also affect human well-being.  
28 Nevertheless, the following types of evidence indicate that the harmful effects of the  
29 degradation of ecosystem services on livelihoods, health, and local and national economies  
30 are substantial.

- 31     ▪ *Most resource management decisions are most strongly influenced by ecosystem*  
32 *services entering markets; as a result, the nonmarketed benefits are often lost or*  
33 *degraded. These nonmarketed benefits are often high and sometimes more valuable*  
34 *than the marketed ones.* For example, one of the most comprehensive studies to date,  
35 which examined the marketed and nonmarketed economic values associated with  
36 forests in eight Mediterranean countries, found that timber and fuelwood generally  
37 accounted for less than a third of total economic value of forests in each country. (See  
38 Figure 8.) Values associated with non-timber forest products, recreation, hunting,  
39 watershed protection, carbon sequestration, and passive use (values independent of  
40 direct uses) accounted for between 25% and 96% of the total economic value of the  
41 forests.
- 42     ▪ *The total economic value associated with managing ecosystems more sustainably is*  
43 *often higher than the value associated with the conversion of the ecosystem through*  
44 *farming, logging, or other intensive uses.* Relatively few studies have compared the  
45 total economic value (including values of both marketed and nonmarketed ecosystem  
46 services) of ecosystems under alternate management regimes, but some of the studies  
47

1 that do exist have found the benefit of managing the ecosystem more sustainably  
2 exceeded that of converting the ecosystem. (See Figure 9.)  
3

- 4 ■ *The economic and public health costs associated with damage to ecosystem services*  
5 *can be substantial.*
  - 6 ○ The early 1990s collapse of the Newfoundland cod fishery due to overfishing  
7 resulted in the loss of tens of thousands of jobs and has cost at least \$2 billion in  
8 income support and retraining.
  - 9 ○ In 1996, the costs to U.K. agriculture associated with damage to water (pollution,  
10 eutrophication), air (emissions of greenhouse gases), soil (off-site erosion damage,  
11 carbon dioxide loss), and biodiversity was \$2.6 billion, or 9% of average yearly  
12 gross farm receipts for the 1990s. Similarly, the damage costs of freshwater  
13 eutrophication alone in England and Wales (involving factors including reduced  
14 value of waterfront dwellings, water treatment costs, reduced recreational value of  
15 water bodies, and tourism losses) was estimated to be \$105–160 million per year  
16 in the 1990s, with an additional \$77 million a year being spent to address those  
17 damages.
  - 18 ○ The incidence of diseases of marine organisms and the emergence of new  
19 pathogens is increasing, and some of these, such as the tropical fish disease  
20 ciguatera, harm human health. Episodes of harmful (including toxic) algal blooms  
21 in coastal waters are increasing in frequency and intensity, harming other marine  
22 resources such as fisheries as well as human health. In a particularly severe  
23 outbreak in Italy in 1989, harmful algal blooms cost the coastal aquaculture  
24 industry \$10 million and the Italian tourism industry \$11.4 million.
  - 25 ○ The frequency and impact of floods and fires has increased significantly in the  
26 past 50 years, in part due to ecosystem changes. Examples are the increased  
27 susceptibility of coastal populations to tropical storms when mangrove forests are  
28 cleared and the increase in downstream flooding that followed land use changes in  
29 the upper Yangtze River. Annual economic losses from extreme events increased  
30 tenfold from the 1950s to approximately \$70 billion in 2003, of which natural  
31 catastrophes (floods, fires, storms, drought, earthquakes) accounted for 84% of  
32 insured losses.
- 33 ■ *The impact of the loss of cultural services is particularly difficult to measure, but it is*  
34 *especially important for some people.* Human cultures, knowledge systems, religions,  
35 and social interactions have been strongly influenced by ecosystems. A number of the  
36 MA sub-global assessments found that spiritual and cultural values of ecosystems  
37 were as important as other services for many local communities, both in developing  
38 countries (the importance of sacred groves of forest in India, for example) and  
39 industrial ones (the importance of urban parks, for instance).  
40

41 **The degradation of ecosystem services represents loss of a capital asset.** [3] Both  
42 renewable resources such as ecosystem services and nonrenewable resources such as mineral  
43 deposits, soil nutrients, and fossil fuels are capital assets. Yet traditional national accounts do  
44 not include measures of resource depletion or of the degradation of these resources. As a  
45 result, a country could cut its forests and deplete its fisheries, and this would show only as a  
46 positive gain in GDP (a measure of current well-being) without registering the corresponding  
47 decline in assets (wealth) that is the more appropriate measure of future well-being.  
48 Moreover, many ecosystem services (such as fresh water in aquifers and the use of the

1 atmosphere as a sink for pollutants) are available freely to those who use them, and so again  
2 their degradation is not reflected in standard economic measures.

3 When estimates of the economic losses associated with the depletion of natural assets are  
4 factored into measurements of the total wealth of nations, they significantly change the  
5 balance sheet of countries with economies significantly dependent on natural resources. For  
6 example, countries such as Ecuador, Ethiopia, Kazakhstan, Democratic Republic of Congo,  
7 Trinidad and Tobago, Uzbekistan, and Venezuela that had positive growth in net savings in  
8 2001, reflecting a growth in the net wealth of the country, actually experienced a loss in net  
9 savings when depletion of natural resources (energy and forests) and estimated damages from  
10 carbon emissions (associated with contributions to climate change) were factored into the  
11 accounts.

12 **While degradation of one service may sometimes be warranted to produce a gain in**  
13 **another service, more degradation of ecosystem services takes place than is in society's**  
14 **interests because many of the services degraded are "public goods."** [3] Although  
15 people benefit from ecosystem services such as the regulation of air and water quality or the  
16 presence of an aesthetically pleasing landscape, there is no market for these services and no  
17 one person has an incentive to pay to maintain the good. And when an action results in the  
18 degradation of a service that harms another individual, no market mechanism exists (nor, in  
19 many cases, could it exist) to ensure that the individuals harmed are compensated for the  
20 damages they suffer.

21 **It is difficult to assess the implications of ecosystem changes and to manage ecosystems**  
22 **effectively because many of the effects are slow to become apparent, because they may**  
23 **be expressed primarily at some distance from where the ecosystem was changed, and**  
24 **because the costs and benefits of changes often accrue to different sets of stakeholders.**  
25 [7] Substantial inertia (delay in the response of a system to a disturbance) exists in ecological  
26 systems. As a result, long time lags often occur between a change in a driver and the time  
27 when the full consequences of that change become apparent. For example, phosphorus is  
28 accumulating in large quantities in many agricultural soils, threatening rivers, lakes, and  
29 coastal oceans with increased eutrophication (a process whereby excessive plant growth  
30 depletes oxygen in the water). But it may take years or decades for the full impact of the  
31 phosphorus to become apparent through erosion and other processes. Similarly, it will take  
32 centuries for global temperatures to reach equilibrium with changed concentrations of  
33 greenhouse gases in the atmosphere and even more time for biological systems to respond to  
34 the changes in climate.

35 Moreover, some of the impacts of ecosystem changes may be experienced only at some  
36 distance from where the change occurred. For example, changes in upstream catchments  
37 affect water flow and water quality in downstream regions; similarly, the loss of an important  
38 fish nursery area in a coastal wetland may diminish fish catch some distance away. Both the  
39 inertia in ecological systems and the spatial separation of costs and benefits of ecosystem  
40 changes often result in situations where the individuals experiencing harm from ecosystem  
41 changes (future generations, say, or downstream landowners) are not the same as the  
42 individuals gaining the benefits. These temporal and spatial patterns make it extremely  
43 difficult to fully assess costs and benefits associated with ecosystem changes or to attribute  
44 costs and benefits to different stakeholders. Moreover, the institutional arrangements now in  
45 place to manage ecosystems are poorly designed to cope with these challenges.

1 **Increased Likelihood of Nonlinear (Stepped) and Potentially Abrupt Changes in**  
2 **Ecosystems**

3 **There is established but incomplete evidence that changes being made in ecosystems are**  
4 **increasing the likelihood of nonlinear and potentially abrupt changes in ecosystems,**  
5 **with important consequences for human well-being.** [7] Changes in ecosystems generally  
6 take place gradually. Some changes are nonlinear, however: once a threshold is crossed, the  
7 system changes to a very different state. And these nonlinear changes are sometimes abrupt;  
8 they can also be large in magnitude and difficult, expensive, or impossible to reverse.  
9 Capabilities for predicting some nonlinear changes are improving, but for most ecosystems  
10 and for most potential nonlinear changes, science cannot predict the thresholds at which the  
11 change will be encountered. Examples of large-magnitude nonlinear changes include:

- 12     ▪ *Disease emergence.* The almost instantaneous outbreak of SARS in different parts of  
13     the world is an example of such potential.
- 14     ▪ *Eutrophication and hypoxia.* Once a threshold of nutrient loading is achieved,  
15     changes in freshwater and coastal ecosystems can be abrupt and extensive, creating  
16     harmful algal blooms (including blooms of toxic species) and sometimes leading to  
17     the formation of oxygen-depleted zones, killing all animal life.
- 18     ▪ *Fisheries collapse.* For example, the Atlantic cod stocks off the east coast of  
19     Newfoundland collapsed in 1992, forcing the closure of the fishery after hundreds of  
20     years of exploitation. (See Figure 10.) Most important, depleted stocks may not  
21     recover even if harvesting is significantly reduced or eliminated entirely.
- 22     ▪ *Species introductions and losses.* The introduction of the zebra mussel into aquatic  
23     systems in the United States, for instance, resulted in the extirpation of native clams in  
24     Lake St. Clair and annual costs of \$100 million to the power industry and other users.
- 25     ▪ *Regional climate change.* Deforestation generally leads to decreased rainfall. Since  
26     forest existence crucially depends on rainfall, the relationship between forest loss and  
27     precipitation decrease can form a positive feedback, which, under certain conditions,  
28     can lead to a nonlinear change in forest cover.

29 **The growing bushmeat trade poses particularly significant threats associated with**  
30 **nonlinear changes.** [7] Growth in the use and trade of bushmeat is placing increasing  
31 pressure on many species, especially in Africa and Asia. Once this pressure exceeds levels of  
32 sustainable harvest, the populations of the harvested species are likely to decline rapidly.  
33 This will place them at risk of extinction and also result in significant harm to the food supply  
34 of people dependent on these resources. At the same time, the bushmeat trade involves  
35 relatively high levels of interaction between humans and some relatively closely related wild  
36 animals that are eaten, and this increases the risk of emergence of new and serious pathogens,  
37 as took place in the case of HIV/AIDs. Given the speed and magnitude of international travel  
38 today, new pathogens could spread rapidly around the world.

39 **The increased likelihood of these non-linear changes stems from the loss of biodiversity**  
40 **and growing pressures from multiple direct drivers of ecosystem change.** [7] The loss of  
41 species and genetic diversity decreases the resilience of ecosystems, which is their ability to  
42 maintain particular ecosystem services as conditions change. In addition, growing pressures  
43 from drivers such as overharvesting, climate change, invasive species, and nutrient loading  
44 push ecosystems toward thresholds that they might otherwise not encounter.

45

1 *Exacerbation of Poverty for Some People and Contribution to Growing Inequities and*  
2 *Disparities across Groups of People*

3 **Despite the progress achieved in increasing the production and use of some ecosystem**  
4 **services, levels of poverty remain high, inequities are growing, and many people still do**  
5 **not have a sufficient supply of or access to ecosystem services. [3]**

- 6     ▪ In 2001, just over 1 billion people survived on less than \$1 per day of income, with  
7       roughly 70% of them in rural areas where they are highly dependent on agriculture,  
8       grazing, and hunting for subsistence.
- 9     ▪ Inequality in income and other measures of human well-being has increased over the  
10       past decade. A child born in sub-Saharan Africa is 20 times more likely to die before  
11       age 5 than a child born in an industrial country, and this disparity is higher than it was  
12       a decade ago. During the 1990s, 21 countries experienced declines in their rankings in  
13       the Human Development Index (an aggregate measure of economic well-being,  
14       health, and education); 14 of them were in sub-Saharan Africa.
- 15     ▪ Despite the growth in per capita food production in the past four decades, an  
16       estimated 856 million people were undernourished in 2000–02, up 32 million from  
17       the period 1995–97. South Asia and sub-Saharan Africa, the regions with the largest  
18       numbers of undernourished people, are also the regions where growth in per capita  
19       food production has been the slowest. Most notably, per capita food production has  
20       declined in sub-Saharan Africa.
- 21     ▪ Some 1.1 billion people still lack access to improved water supply, and more than 2.6  
22       billion lack access to improved sanitation. Water scarcity affects roughly 1–2 billion  
23       people worldwide. Since 1960, ratio of water use to accessible supply has grown by  
24       20% per decade.

25 **The degradation of ecosystem services is harming many of the world’s poorest people**  
26 **and is sometimes the principal factor causing poverty. [3, 6]** Despite the fact that  
27 ecosystem changes such as increased food production have helped lift hundreds of millions of  
28 people out of poverty, these changes have harmed many other communities whose plight has  
29 been largely overlooked.

- 30     ▪ Half the urban population in Africa, Asia, Latin America, and the Caribbean suffers  
31       from one or more diseases associated with inadequate water and sanitation.  
32       Worldwide, approximately 1.8 million people die annually as a result of inadequate  
33       water, sanitation, and hygiene.
- 34     ▪ The declining state of capture fisheries is reducing an inexpensive source of protein in  
35       developing countries. Per capita fish consumption in developing countries, excluding  
36       China, declined between 1985 and 1997.

37  
38 **The pattern of “winners” and “losers” associated with ecosystem changes—and in**  
39 **particular the impact of ecosystem changes on poor people, women, and indigenous**  
40 **peoples—has not been adequately taken into account in management decisions. [3, 6]**  
41 Changes in ecosystems typically yield benefits for some people and exact costs on others who  
42 may either lose access to resources or livelihoods or be affected by externalities associated  
43 with the change. For several reasons, groups such as the poor, women, and indigenous  
44 communities have tended to be harmed by these changes.

- 45     ▪ Many changes in ecosystem management have involved the privatization of what  
46       were formerly common pool resources. Individuals who depended on those resources  
47       (such as indigenous peoples, forest-dependent communities, and other groups

1 relatively marginalized from political and economic sources of power) have often lost  
2 rights to the resources.

- 3 ■ Some of the people and places affected by changes in ecosystems and ecosystem  
4 services are highly vulnerable and poorly equipped to cope with the major changes in  
5 ecosystems that may occur. Highly vulnerable groups include those whose needs for  
6 ecosystem services already exceed the supply, such as people lacking adequate clean  
7 water supplies, and people living in areas with declining per capita agricultural  
8 production.
- 9 ■ Significant differences between the roles and rights of men and women in developing  
10 countries lead to increased vulnerability of women to changes in ecosystem services.
- 11 ■ The reliance of the rural poor on ecosystem services is rarely measured and thus  
12 typically overlooked in national statistics and poverty assessments, resulting in  
13 inappropriate strategies that do not take into account the role of the environment in  
14 poverty reduction. For example, a recent study that synthesized data from 17  
15 countries found that 22% of household income for rural communities in forested  
16 regions comes from sources typically not included in national statistics, such as  
17 harvesting wild food, fuelwood, fodder, medicinal plants, and timber. These activities  
18 generated a much higher proportion of poorer families' total income, and this income  
19 was of particular significance in periods of both predictable and unpredictable  
20 shortfalls in other livelihood sources.

21 **Development prospects in dryland regions of developing countries are especially**  
22 **dependent on actions to avoid the degradation of ecosystems and slow or reverse**  
23 **degradation where it is occurring.** [3, 5] Dryland systems cover about 41% of Earth's land  
24 surface and more than 2 billion people inhabit them, 90% of whom are in developing  
25 countries. Dryland ecosystems (encompassing both rural and urban regions of drylands)  
26 experienced the highest population growth rate in the 1990s of any of the systems examined  
27 in the MA. (See Figure 11.) Although drylands are home to about one third of the human  
28 population, they have only 8% of the world's renewable water supply. Given the low and  
29 variable rainfall, high temperatures, low soil organic matter, and poor potential for  
30 infrastructure (low population densities), people living in drylands face many challenges.  
31 They also tend to have the lowest levels of human well-being, including the lowest per capita  
32 GDP and the highest infant mortality rates.

33 The combination of high variability in environmental conditions and relatively high levels of  
34 poverty leads to situations where people can be highly vulnerable to changes in ecosystems,  
35 although the presence of these conditions has led to the development of very resilient land  
36 management strategies. Pressures on dryland ecosystems already exceed sustainable levels  
37 for some ecosystem services, such as water supply, and are growing. Per capita water  
38 availability is currently only two thirds of the level required for minimum levels of human  
39 well-being. Approximately 10–20% of the world's drylands are degraded (*medium*  
40 *certainty*). Despite these tremendous challenges, people living in drylands and their land  
41 management systems have a proven resilience and the capability of preventing land  
42 degradation, although this can be either undermined or enhanced by public policies and  
43 development strategies.

44 **Wealthy populations cannot be fully insulated from the degradation of ecosystem**  
45 **services.** [3] Agriculture, fisheries, and forestry once formed the bulk of national economies,  
46 and the control of natural resources dominated policy agendas. But while these natural  
47 resource industries are often still important, the relative economic and political significance

1 of other industries in industrial countries has grown over the past century as a result of the  
2 ongoing transition from agricultural to industrial and service economies, urbanization, and  
3 the development of new technologies to increase the production of some services and provide  
4 substitutes for others. Nevertheless, the degradation of ecosystem services influences human  
5 well-being in industrial regions and among wealthy populations in developing countries in  
6 many ways:

- 7     ▪ The physical, economic, or social impacts of ecosystem service degradation may  
8 cross boundaries. (See Figure 12.) For example, land degradation or fires in one  
9 country can degrade air quality (dust and smoke) in other countries nearby.  
10 Degradation of ecosystem services exacerbates poverty in developing countries,  
11 which can affect neighboring industrial countries by slowing regional economic  
12 growth and contributing to the outbreak of conflicts or the migration of refugees.
- 13     ▪ Many sectors of industrial countries still depend directly on ecosystem services. The  
14 collapse of fisheries, for example, has harmed many communities in industrial  
15 countries.
- 16     ▪ Wealthy populations of people are insulated from the harmful effects of some aspects  
17 of ecosystem degradation, but not all. For example, substitutes are typically not  
18 available when cultural services are lost.
- 19     ▪ Even though the relative economic importance of agriculture, fisheries, and forestry is  
20 declining in industrial countries, the importance of other ecosystem services such as  
21 aesthetic enjoyment and recreational options is growing.

23 **Finding #3: The degradation of ecosystem services could grow significantly worse**  
24 **during the first half of this century and is a barrier to achieving the Millennium**  
25 **Development Goals.**

26 The MA developed four scenarios to explore plausible futures for ecosystems and human  
27 well-being. (See Box 1.) The scenarios explored two global development paths, one in  
28 which the world becomes increasingly globalized and the other in which it becomes  
29 increasingly regionalized, as well as two different approaches to ecosystem management, one  
30 in which actions are reactive and most problems are addressed only after they become  
31 obvious and the other in which ecosystem management is proactive and policies deliberately  
32 seek to maintain ecosystem services for the long term.

33  
34 **Most of the direct drivers of degradation in ecosystem services currently remain**  
35 **constant or are growing in intensity in most ecosystems. (See Figure 13.) In all four MA**  
36 **scenarios, the pressures on ecosystems are projected to continue to grow during the first**  
37 **half of this century.** [4, 5] The most important direct drivers of change in ecosystem  
38 services are habitat change (land use change and physical modification of rivers or water  
39 withdrawal from rivers), overexploitation, invasive alien species, pollution, and climate  
40 change. These direct drivers are often synergistic. For example, in some locations land use  
41 change can result in greater nutrient loading (if the land is converted to high-intensity  
42 agriculture), increased climate forcing (if forest is cleared), and increased numbers of  
43 invasive species (due to the disturbed habitat).

- 44     ▪ *Habitat transformation, particularly from conversion to agriculture:* Under the MA  
45 scenarios, a further 10–20% of grassland and forestland is projected to be converted  
46 between 2000 and 2050 (primarily to agriculture), as Figure 2 illustrated. The  
47 projected land conversion is concentrated in low-income countries and arid regions.  
48 (Forest cover is projected to continue to increase within industrial countries.)

### Box 1. MA Scenarios

The MA developed four scenarios to explore plausible futures for ecosystems and human well-being:

*Global Orchestration* – This scenario depicts a globally connected society that focuses on global trade and economic liberalization and takes a reactive approach to ecosystem problems but that also takes strong steps to reduce poverty and inequality and to invest in public goods such as infrastructure and education.

*Order from Strength* – This scenario represents a regionalized and fragmented world, concerned with security and protection, emphasizing primarily regional markets, paying little attention to public goods, and taking a reactive approach to ecosystem problems.

*Adapting Mosaic* – In this scenario, regional watershed-scale ecosystems are the focus of political and economic activity. Local institutions are strengthened and local ecosystem management strategies are common; societies develop a strongly proactive approach to the management of ecosystems.

*TechnoGarden* – This scenario depicts a globally connected world relying strongly on environmentally sound technology, using highly managed, often engineered, ecosystems to deliver ecosystem services, and taking a proactive approach to the management of ecosystems in an effort to avoid problems.

The scenarios are not predictions; instead they were developed to explore the unpredictable and uncontrollable features of change in ecosystem services and a number of socioeconomic factors. No scenario represents business as usual, although all begin from current conditions and trends.

Both quantitative models and qualitative analyses were used to develop the scenarios. For some drivers (such as economic growth, land use change, and carbon emissions) and ecosystem services (water withdrawals, food production), quantitative projections were calculated using established, peer-reviewed global models. Other drivers (such as rates of technological change), ecosystem services (particularly supporting and cultural services, such as soil formation and recreational opportunities), and human well-being indicators (such as human health and social relations), for which there are no appropriate global models, were estimated qualitatively. In general, the quantitative models used for these scenarios addressed incremental changes but failed to address thresholds, risk of extreme events, or impacts of large, extremely costly, or irreversible changes in ecosystem services. These phenomena were addressed qualitatively by considering the risks and impacts of large but unpredictable ecosystem changes in each scenario.

- 1     ▪ *Overexploitation, especially overfishing:* In some marine systems the biomass of  
2     targeted species and those caught incidentally (bycatch) has been reduced by up to  
3     one or more orders of magnitude from preindustrial fishing levels, and the fish being  
4     harvested are increasingly coming from the less valuable lower trophic levels as  
5     populations of higher trophic level species are depleted, as shown in Figure 6. These  
6     pressures continue to grow in all the MA scenarios.
- 7     ▪ *Invasive alien species:* The spread of invasive alien species and disease organisms  
8     continues to increase because of growing trade and travel, with significant harmful  
9     consequences to native species and many ecosystem services.
- 10    ▪ *Pollution, particularly nutrient loading:* Humans have already doubled the flow of  
11    reactive nitrogen on the continents, and some projections suggest that this may  
12    increase by roughly a further two thirds by 2050. (See Figure 14.) The MA scenarios  
13    project that the global flux of nitrogen to coastal ecosystems will increase by a further  
14    10–20% by 2030 (*medium certainty*), with almost all of this increase occurring in  
15    developing countries. Ecological and environmental effects of excessive flows of

1 nitrogen include eutrophication of freshwater and coastal marine ecosystems,  
2 contribution to acid rain with effects on both freshwater and terrestrial ecosystems,  
3 loss of biodiversity in both aquatic and terrestrial ecosystems, creation of ground-level  
4 ozone (which leads to loss of agricultural and forest productivity), destruction of  
5 ozone in the stratosphere (which leads to depletion of the ozone layer and increased  
6 UV-B radiation on Earth), and contribution to global warming. The resulting health  
7 effects include the consequences of ozone pollution on asthma and respiratory  
8 function, increased allergies and asthma due to increased pollen production, risk of  
9 blue-baby syndrome, increased risk of cancer and other chronic diseases from nitrate  
10 in drinking water, and increased risk of a variety of pulmonary and cardiac diseases  
11 from production of fine particles in the atmosphere.

- 12 ■ *Anthropogenic Climate Change*: Observed recent changes in climate, especially  
13 warmer regional temperatures, have already had significant impacts on biodiversity  
14 and ecosystems, including causing changes in species distributions, population sizes,  
15 the timing of reproduction or migration events, and an increase in the frequency of  
16 pest and disease outbreaks. Many coral reefs have undergone major, although often  
17 partially reversible, bleaching episodes when local sea surface temperatures have  
18 increased by 1° Celsius during a single season.

19  
20 By the end of the century, climate change and its impacts may be the dominant direct  
21 driver of biodiversity loss and changes in ecosystem services globally. Harm to  
22 biodiversity will grow worldwide with increasing rates of change in climate and  
23 increasing absolute amounts of change. In contrast, some ecosystem services in some  
24 regions may initially be enhanced by projected changes in climate (such as increases  
25 in temperature or precipitation), and thus these regions may experience net benefits at  
26 low levels of climate change. As climate change becomes more severe, however, the  
27 harmful impacts on ecosystem services outweigh the benefits in most regions of the  
28 world. The balance of scientific evidence suggests that there will be a significant net  
29 harmful impact on ecosystem services worldwide if global mean surface temperature  
30 increases more than 2° Celsius above preindustrial levels or at rates greater than 0.2°  
31 Celsius per decade (*medium certainty*).

32 **Under all four MA scenarios, the projected changes in drivers result in significant**  
33 **growth in consumption of ecosystem services, continued loss of biodiversity, and further**  
34 **degradation of some ecosystem services.** [5]

- 35 ■ During the next 50 years, demand for food is projected to grow by 70–80% under the  
36 MA scenarios, and demand for water by between 30% and 85%. Water withdrawals  
37 in developing countries are projected to increase significantly under the scenarios,  
38 although these are projected to decline in industrial countries (*medium certainty*).
- 39 ■ Food security is not achieved under the MA scenarios by 2050, and child malnutrition  
40 would be difficult to eradicate (and is projected to increase in some regions in some  
41 MA scenarios) despite increasing food supply and more diversified diets (*medium*  
42 *certainty*).
- 43 ■ A severe deterioration of the services provided by freshwater resources (such as  
44 aquatic habitat, fish production, and water supply for households, industry, and  
45 agriculture) is found in the scenarios that are reactive to environmental problems.  
46 Less severe but still important declines are expected in the scenarios that are more  
47 proactive about environmental problems (*medium certainty*).
- 48 ■ Habitat loss and other ecosystem changes are projected to lead to a decline in local  
49 diversity of native species in all four MA scenarios by 2050 (*high certainty*).

1 Globally, the equilibrium number of plant species is projected to be reduced by  
2 roughly 10–15% as the result of habitat loss alone over the period of 1970 to 2050 in  
3 the MA scenarios (*low certainty*), and other factors such as overharvesting, invasive  
4 species, pollution, and climate change will further increase the rate of extinction.

5 **The degradation of ecosystem services poses a significant barrier to the achievement of**  
6 **the Millennium Development Goals and to the MDG targets for 2015.** [3] The eight  
7 Millennium Development Goals adopted by the United Nations in 2000 aim to improve  
8 human well-being by reducing poverty, hunger, child and maternal mortality, by ensuring  
9 education for all, by controlling and managing diseases, by tackling gender disparity, by  
10 ensuring environmental sustainability, and by pursuing global partnerships. Under each of  
11 the MDGs, countries have agreed to targets to be achieved by 2015. The regions facing the  
12 greatest challenges in achieving these targets coincide with the regions facing the greatest  
13 problems of ecosystem degradation: sub-Saharan Africa, Central Asia, parts of South and  
14 Southeast Asia, and some regions in Latin America.

15  
16 Although socioeconomic policy changes will play a primary role in achieving most of the  
17 MDGs, many of the targets (and goals) are unlikely to be achieved without significant  
18 improvement in management of ecosystems. The role of ecosystem changes in exacerbating  
19 poverty (Goal 1, Target 1) for some groups of people has been described already, and the  
20 goal of environmental sustainability (Goal 7) cannot be achieved as long as most ecosystem  
21 services are being degraded. Progress toward two other MDGs is particularly dependent on  
22 sound ecosystem management:

- 23 ▪ Hunger (Goal 1, Target 2): All four MA scenarios project progress in the elimination  
24 of hunger but at rates far slower than needed to attain the internationally agreed target  
25 of halving, between 1990 and 2015, the share of people suffering from hunger.  
26 Moreover, the improvements are slowest in the regions in which the problems are  
27 greatest: South Asia and sub-Saharan Africa.
- 28 ▪ Disease (Goal 6): Changes in ecosystems influence the abundance of human  
29 pathogens such as malaria and cholera as well as the risk of emergence of new  
30 diseases. Malaria is responsible for 11% of the disease burden in Africa, and it is  
31 estimated that Africa's GDP could have been \$100 billion larger in 2000 (roughly a  
32 25% increase) if malaria had been eliminated 35 years ago. The following diseases  
33 are ranked as high priority for their large global burden of disease and their high  
34 sensitivity to ecological change: malaria, schistosomiasis, lymphatic filariasis,  
35 Japanese encephalitis, dengue fever, leishmaniasis, Chagas disease, meningitis,  
36 cholera, West Nile virus, and Lyme disease. In the more promising MA scenarios,  
37 progress toward Goal 6 is achieved, but under *Order from Strength* it is plausible that  
38 health and social conditions for the North and South could diverge, with disastrous  
39 health trends for many low-income regions.

40  
41 **Finding #4: The challenge of reversing the degradation of ecosystems while meeting**  
42 **increasing demands for their services can be met under some scenarios involving**  
43 **significant policy and institutional changes, but these changes are large and not**  
44 **currently under way. Many options exist to conserve or enhance specific ecosystem**  
45 **services in ways that reduce negative trade-offs or that provide positive synergies with**  
46 **other ecosystem services.**

1 **Three of the four MA scenarios show that significant changes in policy can mitigate**  
2 **many of the negative consequences of growing pressures on ecosystems, although the**  
3 **changes required are large and not currently under way.** [5] Moreover, in all scenarios  
4 biodiversity continues to be lost and thus the long-term sustainability of actions to mitigate  
5 degradation of ecosystem services is uncertain. Provisioning, regulating, and cultural  
6 ecosystem services are projected to be in worse condition in 2050 than they are today in only  
7 one of the four MA scenarios (*Order from Strength*). At least one of the three categories of  
8 services is in better condition in 2050 than in 2000 in the other three scenarios. (See Figure  
9 15.) The scale of interventions that result in these positive outcomes, however, are  
10 substantial and include significant investments in environmentally sound technology, active  
11 adaptive management, proactive action to address environmental problems before their full  
12 consequences are experienced, major investments in public goods (such as education and  
13 infrastructure), and strong action to reduce economic disparities and eliminate poverty.

14 **Past actions to slow or reverse the degradation of ecosystems have yielded significant**  
15 **benefits, but these improvements have generally not kept pace with growing pressures**  
16 **and demands.** [8] Although most ecosystem services assessed in the MA are being degraded,  
17 the extent of that degradation would have been much greater without responses implemented  
18 in past decades. For example, more than 100,000 protected areas (including strictly protected  
19 areas such as national parks as well as areas managed for the sustainable use of natural  
20 ecosystems, including timber or wildlife harvest) covering about 11.7% of the terrestrial  
21 surface have now been established, and these play an important role in the conservation of  
22 biodiversity and ecosystem services (although important gaps in the distribution of protected  
23 areas remain, particularly in marine and freshwater systems). Technological advances have  
24 also helped lessen the pressure on ecosystems per unit increase in demand for ecosystem  
25 services.

26 **Substitutes can be developed for some but not all ecosystem services, but the cost of**  
27 **substitutes is generally high, and substitutes may also have other negative**  
28 **environmental consequences.** [8] For example, the substitution of vinyl, plastics, and metal  
29 for wood has contributed to relatively slow growth in global timber consumption in recent  
30 years. But while the availability of substitutes can reduce pressure on specific ecosystem  
31 services, they may not always have positive net benefits on the environment. Substitution of  
32 fuelwood by fossil fuels, for example, reduces pressure on forests and lowers indoor air  
33 pollution but it also increases net greenhouse gas emissions. Substitutes are also often  
34 costlier to provide than the original ecosystem services.

35 **Ecosystem degradation can rarely be reversed without actions that address the negative**  
36 **effects or enhance the positive effects of one or more of the five indirect drivers of**  
37 **change: population change (including growth and migration), change in economic**  
38 **activity (including economic growth, disparities in wealth, and trade patterns),**  
39 **sociopolitical factors (including factors ranging from the presence of conflict to public**  
40 **participation in decision-making), cultural factors, and technological change.** [4]  
41 Collectively these factors influence the level of production and consumption of ecosystem  
42 services and the sustainability of the production. Both economic growth and population  
43 growth lead to increased consumption of ecosystem services, although the harmful  
44 environmental impacts of any particular level of consumption depend on the efficiency of the  
45 technologies used to produce the service. Too often, actions to slow ecosystem degradation  
46 do not address these indirect drivers. For example, forest management is influenced more  
47 strongly by actions outside the forest sector, such as trade policies and institutions,

1 macroeconomic policies, and policies in other sectors such as agriculture, infrastructure,  
2 energy, and mining, than by those within it.

3 **An effective set of responses to ensure the sustainable management of ecosystems must**  
4 **address the indirect and drivers just described and must overcome barriers related to**  
5 [8]:

- 6     ▪ Inappropriate institutional and governance arrangements, including the presence of  
7       corruption and weak systems of regulation and accountability.
- 8     ▪ Market failures and the misalignment of economic incentives.
- 9     ▪ Social and behavioral factors, including the lack of political and economic power of  
10       some groups (such as poor people, women, and indigenous peoples) that are  
11       particularly dependent on ecosystem services or harmed by their degradation.
- 12     ▪ Underinvestment in the development and diffusion of technologies that could increase  
13       the efficiency of use of ecosystem services and could reduce the harmful impacts of  
14       various drivers of ecosystem change.
- 15     ▪ Insufficient knowledge (as well as the poor use of existing knowledge) concerning  
16       ecosystem services and management, policy, technological, behavioral, and  
17       institutional responses that could enhance benefits from these services while  
18       conserving resources.

19  
20 All these barriers are further compounded by weak human and institutional capacity related  
21 to the assessment and management of ecosystem services, underinvestment in the regulation  
22 and management of their use, lack of public awareness, and lack of awareness among  
23 decision-makers of both the threats posed by the degradation of ecosystem services and the  
24 opportunities that more sustainable management of ecosystems could provide.

25 **The MA assessed 74 response options for eight ecosystem services and additional**  
26 **responses related to integrated ecosystem management and one driver, climate change.**  
27 Many of these options hold significant promise for overcoming these barriers and conserving  
28 or sustainably enhancing the supply of ecosystem services. Promising options for specific  
29 sectors are shown in Box 2, while cross-cutting responses addressing key obstacles are  
30 described in the remainder of this section. [8]

### 31 *Institutions and Governance*

32 **Changes in institutional and environmental governance frameworks are often required**  
33 **to create the enabling conditions for effective management of ecosystems.** Today's  
34 institutions were not designed to take into account the threats associated with the degradation  
35 of ecosystem services, nor are they well designed to deal with the management of common  
36 pool resources, a characteristic of many ecosystem services. Issues of ownership and access  
37 to resources, rights to participation in decision-making, and regulation of particular types of  
38 resource use or discharge of wastes can strongly influence the sustainability of ecosystem  
39 management and are fundamental determinants of who wins and loses from changes in  
40 ecosystems. Corruption, a major obstacle to effective management of ecosystems, also stems  
41 from weak systems of regulation and accountability.

42 Promising interventions include:

- 43     ▪ *Integration of ecosystem management goals within other sectors and within broader*  
44       *development planning frameworks.* The most important public policy decisions

## Box 2. Promising Responses for Specific Sectors

### Agriculture

- Removal of production subsidies that have adverse economic, social, and environmental effects.
- Investments in agricultural science and technology and natural resource management to support a new agricultural revolution to meet worldwide food needs.
- Use of response policies that recognize the role of women in the production and use of food and that are designed to empower women by providing knowledge and ensuring access to and control of resources necessary for food security.
- Application of a mix of regulatory and incentive- and market-based mechanisms to reduce overuse of nutrients.

### Fisheries and Aquaculture

- Reduction of marine fishing capacity.
- Strict regulation of marine fisheries, especially with regards to fishing quotas.
- Establishment of appropriate regulatory systems to reduce the detrimental environmental impacts of aquaculture.

### Water

- Payments for ecosystem services provided by watersheds.
- Improved allocation of rights to freshwater resources to align incentives with conservation needs.
- Increased transparency of information regarding water management and improved representation of marginalized stakeholders.
- Development of water markets and water pricing.
- Increased emphasis on the use of the natural environment and nonstructural measures for flood control.

### Forestry

- Integration of agreed forest management practices in financial institutions, trade rules, global environment programs, and global security decision-making.
- Empowerment of local initiatives for sustainable use of forest products; these initiatives are collectively more significant than efforts led by governments or international processes but require their support to spread.
- Reform of forest governance and development of country-led, strategically focused national forest programs negotiated by stakeholders.

1 affecting ecosystems are often made by agencies and in policy arenas other than those  
2 charged with protecting ecosystems. For example, the Poverty Reduction Strategy  
3 Papers prepared by developing-country governments in collaboration with the World  
4 Bank and other institutions strongly shape national development priorities, but these  
5 have not taken into account the importance of ecosystems to improving the basic  
6 human capabilities of the poorest.

- 7 ▪ *Increased coordination among multilateral environmental agreements and between*  
8 *environmental agreements and other international economic and social institutions.*  
9 International agreements are indispensable for addressing ecosystem-related concerns  
10 that span national boundaries, but numerous obstacles weaken their current  
11 effectiveness. Steps are now being taken to increase the coordination among these  
12 mechanisms, and this could help to broaden the focus of the array of instruments.

1 However, coordination is also needed between the multilateral environmental  
2 agreements and more politically powerful international institutions, such as economic  
3 and trade agreements, to ensure that they are not acting at cross-purposes.

- 4 ▪ *Increased transparency and accountability of government and private-sector*  
5 *performance on decisions that have an impact on ecosystems, including through*  
6 *greater involvement of concerned stakeholders in decision-making.* Laws, policies,  
7 institutions, and markets that have been shaped through public participation in  
8 decision-making are more likely to be effective and perceived as just. Stakeholder  
9 participation also contributes to the decision-making process because it allows a better  
10 understanding of impacts and vulnerability, the distribution of costs and benefits  
11 associated with trade-offs, and the identification of a broader range of response  
12 options that are available in a specific context. And stakeholder involvement and  
13 transparency of decision-making can increase accountability and reduce corruption.

#### 14 ***Economics and Incentives***

15 **Economic and financial interventions provide powerful instruments to regulate the use**  
16 **of ecosystem goods and services.** Because many ecosystem services are not traded in  
17 markets, markets fail to provide appropriate signals that might otherwise contribute to the  
18 efficient allocation and sustainable use of the services. A wide range of opportunities exists  
19 to influence human behavior to address this challenge in the form of economic and financial  
20 instruments. However, market mechanisms and most economic instruments can only work  
21 effectively if supporting institutions are in place, and thus there is a need to build institutional  
22 capacity to enable more widespread use of these mechanisms.

23 Promising interventions include:

- 24 ▪ *Elimination of subsidies that promote excessive use of ecosystem services (and, where*  
25 *possible, transfer these subsidies to payments for non-marketed ecosystem services).*  
26 Government subsidies paid to the agricultural sectors of OECD countries between  
27 2001 and 2003 averaged over \$324 billion annually, or one third the global value of  
28 agricultural products in 2000. And a significant proportion of this total involved  
29 production subsidies that led to greater food production than the market conditions  
30 warranted, reduced the profitability of agriculture in developing countries, and  
31 promoted overuse of fertilizers and pesticides. Many countries outside the OECD also  
32 have inappropriate input and production subsidies, and inappropriate subsidies are  
33 common in other sectors such as water, fisheries, and forestry. Although removal of  
34 perverse subsidies will produce net benefits, it will not be without costs.  
35 Compensatory mechanisms may be needed for poor people who are adversely  
36 affected by the removal of subsidies, and removal of agricultural subsidies within the  
37 OECD would need to be accompanied by actions designed to minimize adverse  
38 impacts on ecosystem services in developing countries.
- 39 ▪ *Greater use of economic instruments and market-based approaches in the*  
40 *management of ecosystem services.* These include:
  - 41 ○ *Taxes or user fees for activities with “external” costs* (trade-offs not accounted for  
42 in the market). Examples include taxes on excessive application of nutrients or  
43 ecotourism user fees.

- 1           ○ *Creation of markets, including through cap-and-trade systems.* One of the most  
2 rapidly growing markets related to ecosystem services is the carbon market.  
3 Approximately 64 million tons of carbon dioxide equivalent were exchanged  
4 through projects from January to May 2004, nearly as much as during all of 2003.  
5 The value of carbon trades in 2003 was approximately \$300 million. About one  
6 quarter of the trades involved investment in ecosystem services (hydropower or  
7 biomass). It is *speculated* that this market may grow to some \$44 billion by 2010.  
8 The creation of a market in the form of a nutrient trading system may also be a  
9 low-cost way to reduce excessive nutrient loading in the United States.
- 10          ○ *Payment for ecosystem services.* For example, in 1996 Costa Rica established a  
11 nationwide system of conservation payments to induce landowners to provide  
12 ecosystem services. Under this program, Costa Rica brokers contracts between  
13 international and domestic “buyers” and local “sellers” of sequestered carbon,  
14 biodiversity, watershed services, and scenic beauty. Another innovative  
15 conservation financing mechanism is “biodiversity offsets,” whereby developers  
16 pay for conservation activities as compensation for unavoidable harm that a  
17 project causes to biodiversity.
- 18          ○ *Mechanisms to enable consumer preferences to be expressed through markets.*  
19 For example, current certification schemes for sustainable fisheries and forest  
20 practices provide people with the opportunity to promote sustainability through  
21 their consumer choices.

## 22 ***Social and Behavioral Responses***

23  
24 **Social and behavioral responses—including population policy, public education, civil**  
25 **society actions, and empowerment of communities, women, and youth—can be**  
26 **instrumental in responding to the problem of ecosystem degradation.** These are  
27 generally interventions that stakeholders initiate and execute through exercising their  
28 procedural or democratic rights in efforts to improve ecosystems and human well-being.

29 Promising interventions include:

- 30          ▪ *Changes in consumption.* The choices about what individuals consume and how  
31 much are influenced not just by considerations of price but also by behavioral factors  
32 related to culture, ethics, and values. Behavioral changes that could reduce demand  
33 for threatened ecosystem services can be encouraged through actions by governments  
34 (such as education and public awareness programs or the promotion of demand-side  
35 management), industry (commitments to use raw materials that are from sources  
36 certified as being sustainable, for example, or improved product labeling), and civil  
37 society (through raising public awareness).
- 38          ▪ *Communication and education.* Improved communication and education are essential  
39 to achieve the objectives of environmental conventions and the Johannesburg Plan of  
40 Implementation as well as the sustainable management of natural resources more  
41 generally. Both the public and decision-makers can benefit from education  
42 concerning ecosystems and human well-being, but education more generally provides  
43 tremendous social benefits that can help address many indirect drivers of ecosystem  
44 degradation. While the importance of communication and education is well  
45 recognized, providing the human and financial resources to undertake effective work  
46 is a continuing problem.

- 1       ▪ *Empowerment of groups particularly dependent on ecosystem services or affected by*  
2 *their degradation, including women, indigenous peoples, and young people.* Despite  
3 women’s knowledge about the environment and the potential they possess, their  
4 participation in decision-making has often been restricted by economic, social, and  
5 cultural structures. Young people are also key stakeholders in that they will  
6 experience the longer-term consequences of decisions made today concerning  
7 ecosystem services. Indigenous control of traditional homelands is often presented as  
8 having environmental benefits by indigenous peoples and their supporters, although  
9 the primary justification continues to be based on human and cultural rights.

## 10 ***Technological Responses***

11 **Given the growing demands for ecosystem services and other increased pressures on**  
12 **ecosystems, the development and diffusion of technologies designed to increase the**  
13 **efficiency of resource use or reduce the impacts of drivers such as climate change and**  
14 **nutrient loading are essential.** Technological change has been essential for meeting  
15 growing demands for some ecosystem services, and technology holds considerable promise  
16 to help meet future growth in demand. Technologies already exist for reduction of nutrient  
17 pollution at reasonable costs, for example, but new policies are needed for these tools to be  
18 applied on a sufficient scale to slow and ultimately reverse the increase in nutrient loading  
19 (even while increasing nutrient application in relatively poor regions such as sub-Saharan  
20 Africa). However, negative impacts on ecosystems and human well-being have sometimes  
21 resulted from new technologies, and thus careful assessment is needed prior to their  
22 introduction.

23 Promising interventions include:

- 24       ▪ *Promotion of technologies that enable increased crop yields without harmful impacts*  
25 *related to water, nutrient, and pesticide use.* Agricultural expansion will continue to  
26 be one of the major drivers of biodiversity loss well into the twenty-first century.  
27 Development, assessment, and diffusion of technologies that could increase the  
28 production of food per unit area sustainably without harmful trade-offs related to  
29 excessive consumption of water or use of nutrients or pesticides would significantly  
30 lessen pressure on other ecosystem services.
- 31       ▪ *Restoration of ecosystem services.* Ecosystem restoration activities are now common  
32 in many countries. Ecosystems similar to the ones that were present before  
33 conversion can often be established and can provide some of the original ecosystem  
34 services. However, the cost of restoration is generally extremely high compared with  
35 the cost of preventing the degradation of the ecosystem.

## 36 ***Knowledge and Cognitive Responses***

37 **Effective management of ecosystems is constrained both by the lack of knowledge and**  
38 **information about different aspects of ecosystems and by the failure to use adequately**  
39 **the information that does exist in support of management decisions.** [8, 9] Although  
40 sufficient information exists to take many actions that could help conserve ecosystems and  
41 enhance human well-being, major information gaps exist. In most regions, for example,  
42 relatively limited information exists about the status and economic value of most ecosystem  
43 services, and their depletion is rarely tracked in national economic accounts. Limited  
44 information exists about the likelihood of nonlinear changes in ecosystems or the location of

1 thresholds where such changes may be encountered. Basic global data on the extent and  
2 trend in different types of ecosystems and land use are surprisingly scarce. Models used to  
3 project future environmental and economic conditions have limited capability of  
4 incorporating ecological “feedbacks,” including non-linear changes in ecosystems, as well as  
5 behavioral feedbacks such as learning that may take place through adaptive management of  
6 ecosystems.

7 At the same time, decision-makers do not use all of the relevant information that is available.  
8 This is due in part to institutional failures that prevent existing policy-relevant scientific  
9 information from being made available to decision-makers and in part to the failure to  
10 incorporate other forms of knowledge and information (such as traditional knowledge and  
11 practitioners’ knowledge) that are often of considerable value for ecosystem management.

12 Promising interventions include:

13     ▪ *Incorporation of nonmarket values of ecosystems in resource management decisions.*  
14 Most resource management decisions are strongly influenced by considerations of the  
15 monetary costs and benefits of alternative policy choices. Decisions can be improved  
16 if they are informed by the total economic value of alternative management options  
17 and involve deliberative mechanisms that bring to bear noneconomic considerations  
18 as well.

19     ▪ *Use of all relevant forms of knowledge and information in assessments and decision-*  
20 *making, including traditional and practitioners' knowledge.* Effective management  
21 of ecosystems typically requires “place-based” knowledge—that is, information about  
22 the specific characteristics and history of an ecosystem. Traditional knowledge or  
23 practitioners' knowledge held by local resource managers can often be of considerable  
24 value in resource management, but it is too rarely incorporated into decision-making  
25 processes and indeed is often inappropriately dismissed.

26     ▪ *Enhancement of human and institutional capacity for assessing the consequences of*  
27 *ecosystem change for human well-being and acting on such assessments.* Greater  
28 technical capacity is needed for agriculture, forest, and fisheries management. But the  
29 capacity that exists for these sectors, as limited as it is in many countries, is still vastly  
30 greater than the capacity for effective management of other ecosystem services.

31 **A variety of frameworks and methods can be used to make better decisions in the face**  
32 **of uncertainties in data, prediction, context, and scale. Active adaptive management**  
33 **can be a particularly valuable tool for reducing uncertainty about ecosystem**  
34 **management decisions.** Commonly used decision-support methods include cost-benefit  
35 analysis, risk assessment, multicriteria analysis, the precautionary principle, and vulnerability  
36 analysis. Scenarios also provide one means to cope with many aspects of uncertainty, but our  
37 limited understanding of ecological and human response process shrouds any individual  
38 scenario in its own characteristic uncertainty. Active adaptive management is a tool that can  
39 be particularly valuable given the high levels of uncertainty surrounding coupled  
40 socioecological systems. This involves the design of management programs to test  
41 hypotheses about how components of an ecosystem function and interact, thereby reducing  
42 uncertainty about the system more rapidly than would otherwise occur.

43

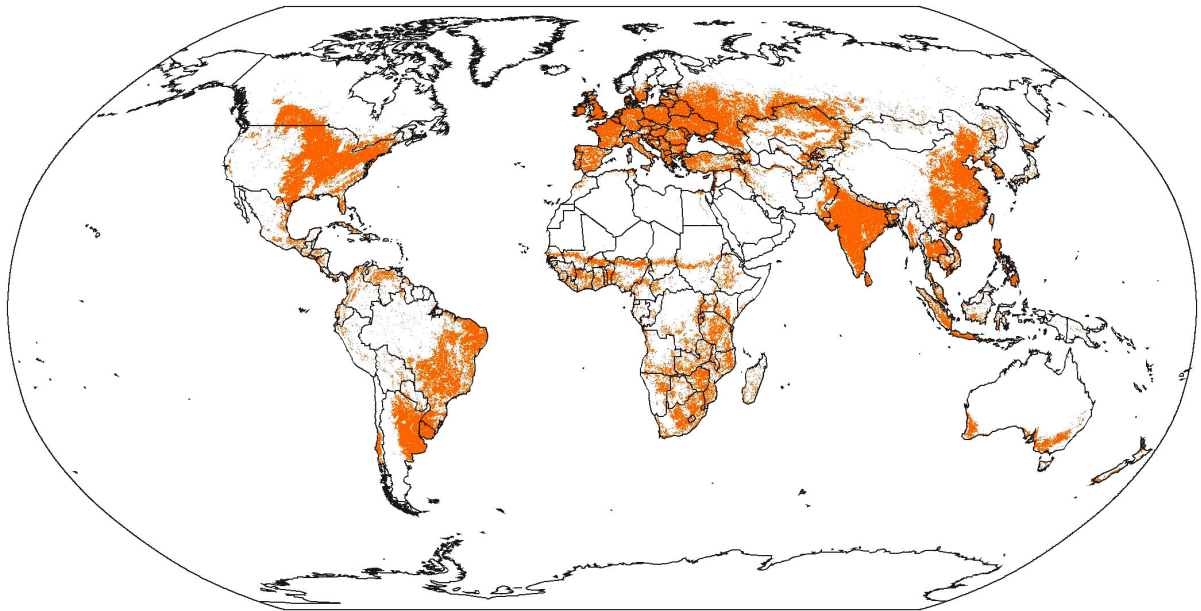

1 **Table 1. Global Status of Ecosystem Services Evaluated in This Assessment.** Status  
 2 indicates whether the condition of the service globally has been enhanced (if the  
 3 productive capacity of the service has been increased, for example) or degraded.  
 4 Definitions of “enhanced” and “degraded” for the four categories of ecosystem services  
 5 are provided in the note below.  
 6

Service	Sub-category	Status	Notes
<b>Provisioning Services</b>			
Food	crops	↑	substantial production increase
	livestock	↑	substantial production increase
	capture fisheries	↓	declining production due to overharvest
	aquaculture	↑	substantial production increase
	wild foods	↓	declining production
Fiber	timber	+/-	forest loss in some regions, growth in others
	cotton, hemp, silk	+/-	declining production of some fibers, growth in others
	wood fuel	↓	declining production
Genetic resources		↓	lost through extinction and crop genetic resource loss
Biochemicals, natural medicines, pharmaceuticals		↓	lost through extinction, overharvest
Water	fresh water	↓	unsustainable use for drinking, industry, and irrigation; amount of hydro energy unchanged, but dams increase our ability to use that energy
<b>Regulating Services</b>			
Air quality regulation		↓	ability of atmosphere to cleanse itself has declined
Climate regulation	global	↑	net source of carbon sequestration since mid-century
	regional and local	↓	preponderance of negative impacts
Water regulation		+/-	varies depending on ecosystem change and location
Erosion regulation		↓	increased soil degradation
Water purification and waste treatment		↓	declining water quality
Disease regulation		+/-	varies depending on ecosystem change
Pest regulation		↓	natural control degraded through pesticide use
Pollination		↓ <sup>a</sup>	apparent global decline in abundance of pollinators
Natural hazard regulation		↓	loss of natural buffers (wetlands, mangroves)
<b>Cultural Services</b>			
Spiritual and religious values		↓	rapid decline in sacred groves and species
Aesthetic values		↓	decline in quantity and quality of natural lands
Recreation and ecotourism		+/-	more areas accessible but many degraded

7  
 8 **Note:** For provisioning services, we define enhancement to mean increased production of the service  
 9 through changes in area over which the service is provided (e.g., spread of agriculture) or increased  
 10 production per unit area. We judge the production to be degraded if the current use exceeds sustainable  
 11 levels. For regulating and supporting services, enhancement refers to a change in the service that leads to  
 12 greater benefits for people (e.g., the service of disease regulation could be improved by eradication of a  
 13 vector known to transmit a disease to people). Degradation of regulating and supporting services means a  
 14 reduction in the benefits obtained from the service, either through a change in the service (e.g., mangrove  
 15 loss reducing the storm protection benefits of an ecosystem) or through human pressures on the service  
 16 exceeding its limits (e.g., excessive pollution exceeding the capability of ecosystems to maintain water  
 17 quality). For cultural services, enhancement refers to a change in the ecosystem features that increase the  
 18 cultural (recreational, aesthetic, spiritual, etc.) benefits provided by the ecosystem.  
 19

1 **Figure 4. Species Extinction Rates.** (Adapted from C4 Fig 4.22) “Fossil Record” refers to  
 2 average extinction rates as estimated from the fossil record. “Past Century—Known  
 3 Species” refers to extinction rates calculated from known extinctions of species (lower  
 4 estimate) or known extinctions plus “possibly extinct” species (upper bound). A species  
 5 is considered to be “possibly extinct” if it is believed by experts to be extinct but  
 6 extensive surveys have not yet been undertaken to confirm its disappearance. “Projected”  
 7 extinctions are model-derived estimates using a variety of techniques, including species-  
 8 area models, rates at which species are shifting to increasingly more threatened  
 9 categories, extinction probabilities associated with the IUCN categories of threat, impacts  
 10 of projected habitat loss on species currently threatened with habitat loss, and correlation  
 11 of species loss with energy consumption. The time frame and species groups involved  
 12 differ among the “projected” estimates, but in general refer to either future loss of species  
 13 based on the level of threat that exists today or current and future loss of species as a  
 14 result of habitat changes taking place over the period of roughly 1970 to 2050. Estimates  
 15 based on the fossil record are *low certainty*; lower-bound estimates for known extinctions  
 16 are *high certainty* and upper-bound estimates are *medium certainty*; lower-bound  
 17 estimates for projected extinctions are *low certainty* and upper bound estimates are  
 18 *speculative*.

1 **Figure 5. Estimated Global Marine Fish Catch, 1950–2001.** (Fig C18.3) In this figure,  
 2 the catch reported by governments is in some cases adjusted to correct for likely errors in  
 3 data.

4  
 5 **Figure 6. Decline in Trophic Level of Fisheries Catch Since 1950.** (Fig C18.??) A  
 6 trophic level of an organism is its position in a food chain. Levels are numbered  
 7 according to how far particular organisms are along the chain from the primary producers  
 8 at level 1, to herbivores (level 2), to predators (level 3), to carnivores or top carnivores  
 9 (level 4 or 5). Fish at higher trophic levels are typically of higher economic value. The  
 10 decline in the trophic level harvested is largely a result of the overharvest of fish at higher  
 11 trophic levels.

12  
 13 **Figure 7. Trend in Mean Depth of Catch Since 1950.** Fisheries catches increasingly  
 14 originate from deep areas. (Data from Fig. C18.5)

15

16

1 **Figure 8. Annual Flow of Benefits from Forests in Selected Mediterranean**  
 2 **Countries.** In most countries, the marketed values of ecosystems associated with timber  
 3 and fuelwood production are less than one third of the total economic value, including  
 4 nonmarketed values such as carbon sequestration, watershed protection, and recreation.

5  
6

1 **Figure 9. Economic Benefits Under Alternate Management Practices** (expressed as  
 2 net present value in dollars per hectare). In each case, the net benefits from the more  
 3 sustainably managed ecosystem (purple bars) are greater than those from the converted  
 4 ecosystem (maroon bars) even though the private (market) benefits would be greater from  
 5 the converted ecosystem. (Where ranges of values are given in the original source, lower  
 6 estimates are plotted here.)

1 **Figure 10. Collapse of Atlantic Cod Stocks Off the East Coast of Newfoundland in**  
2 **1992.** This collapse forced the closure of the fishery after hundreds of years of  
3 exploitation. Until the late 1950s, the fishery was exploited by migratory seasonal fleets  
4 and resident inshore small-scale fishers. From the late 1950s, offshore bottom trawlers  
5 began exploiting the deeper part of the stock, leading to a large catch increase and a  
6 strong decline in the underlying biomass. The stock collapsed to extremely low levels in  
7 the late 1980s and early 1990s, and a moratorium on commercial fishing was declared in  
8 June 1992. A small commercial inshore fishery was reintroduced in 1998, but catch rates  
9 declined and the fishery was closed indefinitely in 2003.

# 1. How have ecosystems changed?

## *Ecosystem Structure*

**The structure of the world's ecosystems changed more rapidly in the second half of the twentieth century than at any time in recorded human history, and virtually all of Earth's ecosystems have now been significantly transformed through human actions.** The most significant change in the structure of ecosystems has been the transformation of approximately one quarter (24%) of Earth's terrestrial surface to cultivated systems (C26.1.2). (See Box 1.1.) More land was converted to cropland since 1945 than in the eighteenth and nineteenth centuries combined (C26.??).

Between 1960 and 2000, reservoir storage capacity quadrupled (C7.2.4); as a result, the amount of water stored behind large dams is estimated to be three to six times the amount held by natural river channels (this excludes natural lakes) (C7.3.2). (See Figure 1.1.) In countries for which sufficient multiyear data are available (encompassing more than half of the present-day mangrove area), approximately 35% of mangroves have been lost in the last two decades (C19.2.1). Roughly 27% of the world's coral reefs were badly degraded or destroyed in the last several decades of the twentieth century (C19.2.1). Box 1.1 and Table 1.1 summarize important characteristics and trends in different ecosystems.

**Although the most rapid changes in ecosystems are now taking place in developing countries, industrial countries historically experienced comparable rates of change.** Croplands expanded rapidly in Europe after 1700 and in North America and the former Soviet Union, particularly after 1850 (C26.1.1). Roughly 70% of the original temperate forests and grasslands and Mediterranean forests had been lost by 1950, largely through conversion to agriculture (C4.4.3). Historically, deforestation has been much more intensive in temperate regions than in the tropics, and Europe is the continent with the smallest fraction of its original forests remaining (C21.4.2). However, changes prior to the industrial era seemed to occur at much slower rates than current transformations.

**The ecosystems and biomes that have been most significantly altered globally by human activity include marine and freshwater ecosystems, temperate broadleaf forests, temperate grasslands, Mediterranean forests, and tropical dry forests.** (See Figure 1.2 and C18, C20.) Within marine systems, the world's demand for food and animal feed over the last 50 years has resulted in fishing pressure so strong that the biomass of both targeted species and those caught incidentally (the "bycatch") has been reduced in much of the world to one tenth of the levels prior to the onset of industrial fishing (C18.ES). Globally, the degradation of fisheries is also reflected in the fact that the fish being harvested are increasingly coming from the less valuable lower trophic levels as populations of higher trophic level species are depleted. (See Figure 1.3.)

Freshwater ecosystems have been modified through the creation of dams and through the withdrawal of water for human use. The construction of dams and other structures along rivers has moderately or strongly affected flows in 60% of the large river systems in the world (C20.4.2). Water removal for human uses has reduced the flow of several major rivers, including the Nile, Yellow, and Colorado Rivers, to the extent that they do not always flow to the sea. As water flows have declined, so have sediment flows, which are the source of nutrients important for the maintenance of estuaries. Worldwide, sediment delivery to estuaries has declined by roughly 30% (C19.ES).

1 Within terrestrial ecosystems, more than two thirds of the area of 2 of the world's 14  
2 major terrestrial biomes (temperate grasslands and Mediterranean forests) and more than  
3 half of the area of four other biomes (tropical dry forests, temperate broadleaf forests,  
4 tropical grassland, and flooded grasslands) had been converted (primarily to agriculture)  
5 by 1990, as Figure 1.3 indicated. Among the major biomes, only tundra and boreal forests  
6 show negligible levels of loss and conversion, although they have begun to be affected by  
7 climate change.

8 **Globally, the rate of conversion of ecosystems has begun to slow largely due to**  
9 **reductions in the rate of expansion of cultivated land, and in some regions**  
10 **(particularly in temperate zones) ecosystems are returning to conditions and species**  
11 **compositions similar to their pre-conversion states. Yet rates of ecosystem**  
12 **conversion remain high or are increasing for specific ecosystems and regions.** Under  
13 the aegis of the MA, the first systematic examination of the status and trends in terrestrial  
14 and coastal land cover was carried out using global and regional datasets. The pattern of  
15 deforestation, afforestation, and dryland degradation between 1980 and 2000 is shown in  
16 Figure 1.4. Opportunities for further expansion of cultivation are diminishing in many  
17 regions of the world as most of the land well-suited for intensive agriculture has been  
18 converted to cultivation (C26.ES). Increased agricultural productivity is also diminishing  
19 the need for agricultural expansion.

20 As a result of these two factors, a greater fraction of land in cultivated systems (areas with  
21 at least 30% of land cultivated) is actually being cultivated, the intensity of cultivation of  
22 land is increasing, fallow lengths are decreasing, and management practices are shifting  
23 from monocultures to polycultures. Since 1950, cropland areas have stabilized in North  
24 America and decreased in Europe and China (C26.1.1). Cropland areas in the Former  
25 Soviet Union have decreased since 1960 (C26.1.1). Within temperate and boreal zones,  
26 forest cover increased by approximately 2.9 million hectares per year in the 1990s, of  
27 which approximately 40% was forest plantations (C21.4.2). In some cases, rates of  
28 conversion of ecosystems have apparently slowed because most of the ecosystem has now  
29 been converted, as is the case with temperate broadleaf forests and Mediterranean forests  
30 (C4.4.3).

### 31 *Ecosystem Processes*

32  
33 **Ecosystem processes, including water, nitrogen, carbon, and phosphorus cycling,**  
34 **changed more rapidly in the second half of the twentieth century than at any time in**  
35 **recorded human history.** Human modifications of ecosystems have changed not only  
36 the structure of the systems (such as what habitats or species are present in a particular  
37 location), but their processes and functioning as well. The capacity of ecosystems to  
38 provide services derives directly from the operation of natural biogeochemical cycles that  
39 in some cases have been significantly modified.

- 40 ▪ *Water Cycle:* Water withdrawals from rivers and lakes for irrigation or for urban or  
41 industrial use doubled between 1960 and 2000 (C7.2.4). (Worldwide, 70% of water  
42 use is for agriculture (C7.2.2).) Large reservoir construction has doubled or tripled  
43 the residence time of river water—the average time, that is, that a drop of water takes  
44 to reach the sea (C7.3.2). Globally, humans use slightly more than 10% of the  
45 available renewable freshwater supply through household, agricultural, and industrial  
46 activities (C7.2.3), although in some regions such as the Middle East and North

1 Africa, humans use 120% of renewable supplies (the excess is obtained through the  
2 use of groundwater supplies at rates greater than their rate of recharge) (C7.2.2).

- 3 ▪ *Carbon Cycle:* Since 1750, the atmospheric concentration of carbon dioxide has  
4 increased by about 34% (from about 280 parts per million to 376 parts in 2003)  
5 (S7.3.1). Approximately 60% of that increase (60 parts per million) has taken place  
6 since 1959. The effect of changes in terrestrial ecosystems on the carbon cycle  
7 reversed during the last 50 years. Those ecosystems were on average a net source of  
8 CO<sub>2</sub> during the nineteenth and early twentieth centuries (primarily due to  
9 deforestation, but with contributions from degradation of agricultural, pasture, and  
10 forestlands) and became a net sink sometime around the middle of the last century  
11 (although carbon losses from land use change continue at high levels) (*high*  
12 *certainty*). Factors contributing to the growth of the role of ecosystems in carbon  
13 sequestration include afforestation, reforestation, and forest management in North  
14 America, Europe, China, and other regions; changed agriculture practices; and the  
15 fertilizing effects of nitrogen deposition and increasing atmospheric CO<sub>2</sub> (*high*  
16 *certainty*) (C13.ES).
- 17 ▪ *Nitrogen Cycle:* The total amount of reactive, or biologically available, nitrogen  
18 created by human activities increased ninefold between 1890 and 1990, with most of  
19 that increase taking place in the second half of the century in association with  
20 increased use of fertilizers (S7.3.2). (See Figures 1.5 and 1.6.) A recent study of  
21 global human contributions to reactive nitrogen flows in 2050 projected that flows  
22 will increase from approximately 165 teragrams of reactive nitrogen in 1999 to 270  
23 teragrams in 2050, an increase of 64% (R9.??). More than half of all the synthetic  
24 nitrogen fertilizer (which was first produced in 1913) ever used on the planet has been  
25 used since 1985 (R9.2). Human activities have now roughly doubled the rate of  
26 creation of reactive N on the land surfaces of Earth (R9.2). The flux of reactive N to  
27 the oceans increased by nearly 80% from 1860 to 1990, from roughly 27 teragrams of  
28 N per year to 48 teragrams in 1990 (R9.??). (This change is not uniform over the  
29 Earth, however, and while some regions such as Labrador and Hudson's Bay in  
30 Canada have seen little if any change, the fluxes from more developed regions such as  
31 the northeastern US, the watersheds of the North Sea in Europe, and the Yellow River  
32 basin in China have increased by 10- to 15-fold)
- 33 ▪ *Phosphorus Cycle:* The use of phosphorus fertilizers and the rate of phosphorus  
34 accumulation in agricultural soils increased nearly threefold between 1960 and 1990,  
35 although the rate has declined somewhat since that time (S7 Fig 7.18). The current  
36 flux of phosphorus to the oceans is now triple that of background rates (approximately  
37 22 teragrams of P per year versus the natural flux of 8 teragrams) (R9.2).

### 38 *Species*

39 A change in an ecosystem necessarily affects the species in the system, and changes in  
40 species affect ecosystem processes.

41 **The distribution of species on Earth is becoming more homogenous.** By homogenous,  
42 we mean that the differences between the set of species at one location on the planet and  
43 the set at another location are, on average, diminishing. The natural process of evolution,  
44 and particularly the combination of natural barriers to migration and local adaptation of

1 species, led to significant differences in the types of species in ecosystems in different  
2 regions. But these regional differences in the planet’s biota are now being diminished.

3 Two factors are responsible for this trend. First, the extinction of species or the loss of  
4 populations results in the loss of the presence of species that had been unique to particular  
5 regions. Second, the rate of invasion or introduction of species into new ranges is already  
6 high and continues to accelerate apace with growing trade and faster transportation. (See  
7 Figure 1.7.) For example, a high proportion of the roughly 100 nonnative species in the  
8 Baltic Sea are native to the North American Great Lakes, and 75% of the recent arrivals  
9 of about 170 nonnative species in the Great Lakes are native to the Baltic Sea (S10.5).  
10 When species decline or go extinct as a result of human activities, they are replaced by a  
11 much smaller number of expanding species that thrive in human-altered environments.  
12 One effect is that in some regions where diversity has been low, the biotic diversity may  
13 actually increase—a result of invasions of nonnative forms. (This is true in continental  
14 areas such as the Netherlands as well as on oceanic islands.)

15 **Across a range of taxonomic groups, either the population size or range or both of**  
16 **the majority of species is currently declining.** Studies of amphibians globally, African  
17 mammals, birds in agricultural lands, British butterflies, Caribbean corals, and fishery  
18 species show the majority of species to be declining in range or number. Exceptions  
19 include species that have been protected in reserves, that have had their particular threats  
20 (such as overexploitation) eliminated, or that tend to thrive in landscapes that have been  
21 modified by human activity (C4.ES).

22 **Between 10% and 30% of mammal, bird, and amphibian species are currently**  
23 **threatened with extinction (*medium to high certainty*), based on IUCN–World**  
24 **Conservation Union criteria for threats of extinction.** As of 2004, comprehensive  
25 assessments of every species within major taxonomic groups have been completed for  
26 only three groups of animals (mammals, birds, and amphibians) and two plant groups  
27 (conifers and cycads, a group of evergreen palm-like plants). Specialists on these groups  
28 have categorized species as “threatened with extinction” if they meet a set of quantitative  
29 criteria involving their population size, the size of area in which they are found, and  
30 trends in population size or area.

31 Under the widely used IUCN criteria for extinction, the vast majority of species  
32 “threatened with extinction” have approximately a 10% chance of going extinct within  
33 100 years (although some long-lived species will persist much longer even though their  
34 small population size and lack of recruitment means that they have a very high likelihood  
35 of extinction). Twelve percent of bird species, 23% of mammals, and 25% of conifers are  
36 currently threatened with extinction; 32% of amphibians are threatened with extinction,  
37 but information is more limited and this may be an underestimate. Higher levels of threat  
38 have been found in the cycads, where 52% are threatened (C4.ES).

39 **Over the past few hundred years, humans have increased the species extinction rate**  
40 **by as much as 1,000 times background rates typical over the planet’s history**  
41 **(*medium certainty*)** (C4.ES, C4.4.2.). (See Figure 1.8.) Extinction is a natural part of  
42 Earth’s history. Most estimates of the total number of species today lie between 5 million  
43 and 30 million, although the overall total could be higher than 30 million if poorly known  
44 groups such as deep-sea organisms, fungi, and microorganisms including parasites have  
45 more species than currently estimated. Species present today only represent 2–4% of all

1 species that have ever lived. The fossil record appears to be punctuated by five major  
2 mass extinctions, the most recent of which occurred 65 million years ago.

3  
4 The average rate of extinction found for marine and mammal fossil species (excluding  
5 extinctions that occurred in the five major mass extinctions) is approximately 0.1–1  
6 extinctions per million species per year. There are approximately 100 documented  
7 extinctions of birds, mammal, and amphibians over the past 100 years, a rate 50–500  
8 times higher than background rates. Including possibly extinct species, the rate is more  
9 than 1,000 times higher than background rates. Although the data and techniques used to  
10 estimate current extinction rates have improved over the past two decades, significant  
11 uncertainty still exists in measuring current rates of extinction because the extent of  
12 extinctions of undescribed taxa is unknown, the status of many described species is  
13 poorly known, it is difficult to document the final disappearance of very rare species, and  
14 there are time lags between the impact of a threatening process and the resulting  
15 extinction.

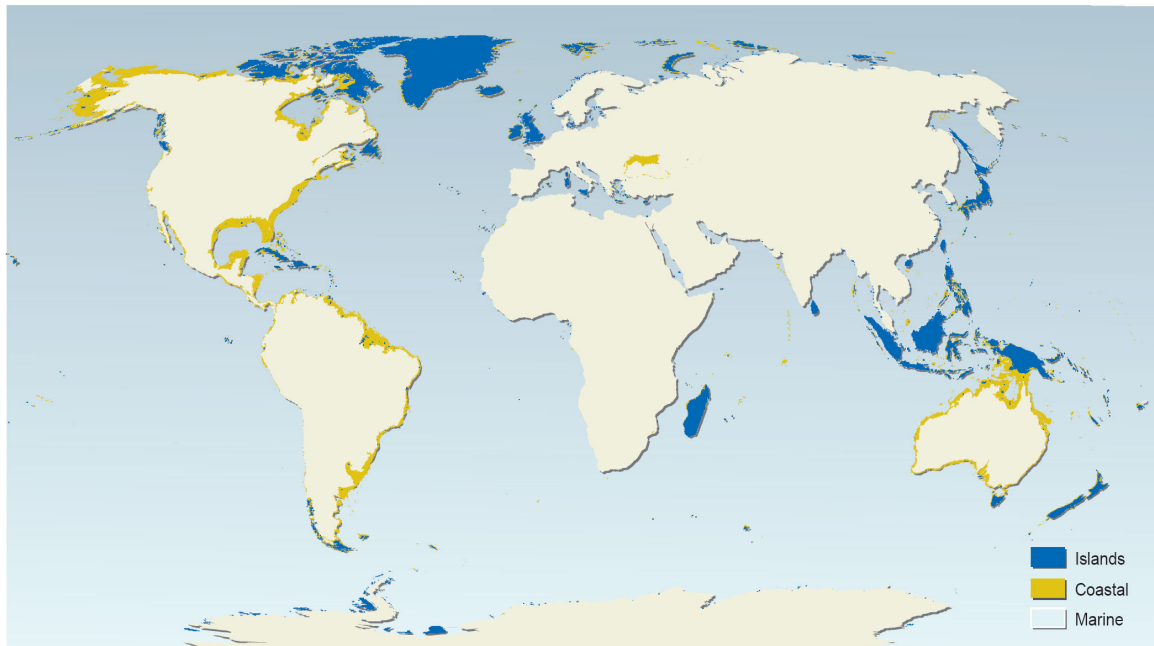

### 16 *Genes*

17  
18 **Genetic diversity has declined globally, particularly among cultivated species.** The  
19 extinction of species and loss of unique populations has resulted in the loss of unique  
20 genetic diversity contained by those species and populations. For wild species, there are  
21 few data on the actual changes in the magnitude and distribution of genetic diversity  
22 (C4.4), although studies have documented declining genetic diversity in wild species that  
23 have been heavily exploited. In cultivated systems, since 1960 there has been a  
24 fundamental shift in the pattern of intra-species diversity in farmers' fields and farming  
25 systems as the crop varieties planted by farmers have shifted from locally adapted and  
26 developed populations (landraces) to more widely adapted varieties produced through  
27 formal breeding systems (modern varieties). Roughly 80% of wheat area in developing  
28 countries and three quarters of the rice area in Asia is planted with modern varieties. (For  
29 other crops, such as maize, sorghum and millet, the proportion of area planted to modern  
30 varieties is far smaller.) (C26.2.1) The on-farm losses of genetic diversity of crops and  
31 livestock have been partially offset by the maintenance of genetic diversity in seed banks.

32

## Box 1.1. Characteristics of the World's Ecological Systems

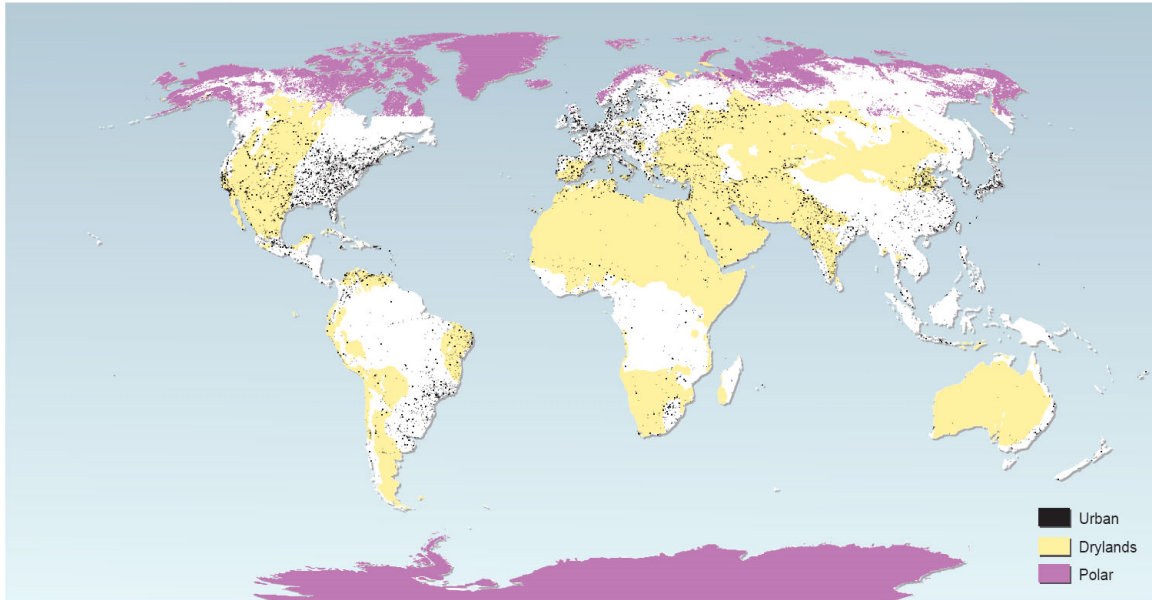

We report assessment findings for 10 categories of the land and marine surface, which we refer to as “systems”: forest, cultivated, dryland, coastal, marine, urban, polar, freshwater, island, and mountain. Each category contains a number of ecosystems. However, ecosystems within each category share a suite of biological, climatic, and social factors that tend to be similar within categories and differ across categories. The MA reporting categories are not spatially exclusive; their areas often overlap. For example, transition zones between forest and cultivated lands are included in both the forest system and cultivated system reporting categories. These reporting categories were selected because they correspond to the regions of responsibility of different government ministries (such as agriculture, water, forestry, and so forth) and because they are the categories used within the Convention on Biological Diversity.

**Marine, Coastal, and Island Systems** [Note: Figure above to include legend with MA system definitions]

- *Marine systems* are the world's oceans. For mapping purposes, the map shows ocean areas where the depth is greater than 50 meters. Global fishery catches from marine systems peaked in the late 1980s and are now declining despite increasing fishing effort (C18.ES).
- *Coastal systems* refer to the interface between ocean and land, extending seawards to about the middle of the continental shelf and inland to include all areas strongly influenced by proximity to the ocean. The map shows the area between 50 meters below mean sea level and 50 meters above the high tide level or extending landward to a distance 100 kilometers from shore. Coastal systems include coral reefs, intertidal zones, estuaries, coastal aquaculture, and sea grass communities. Nearly half of the world's major cities (having more than 500,000 people) are located within 50 kilometers of the coast, and coastal population densities are 2.6 times larger than the density of inland areas. By all commonly used measures, the human well-being of coastal inhabitants is on average much higher than that of inland communities (C19.3.1).
- *Islands* are lands (both continental and oceanic) isolated by surrounding water and with a high proportion of coast to hinterland. For mapping purposes, the MA uses the ESRI ArcWorld Country Boundary dataset, which contains nearly 12,000 islands. Islands smaller than 1.5 hectares are not mapped or included in the statistics. The largest island included is Greenland. The map above includes islands within 2km of the mainland (e.g, Long Island in the United

1 States) but the statistics provided for island systems in this report exclude these islands.  
 2 Island states together with their exclusive economic zones cover 40% of the world's oceans  
 3 (C23.ES). Island systems are especially sensitive to disturbances, and the majority of recorded  
 4 extinctions have occurred on island systems, although this pattern is changing, and over the  
 5 past 20 years as many extinctions have occurred on continents as on islands (C4.ES).  
 6

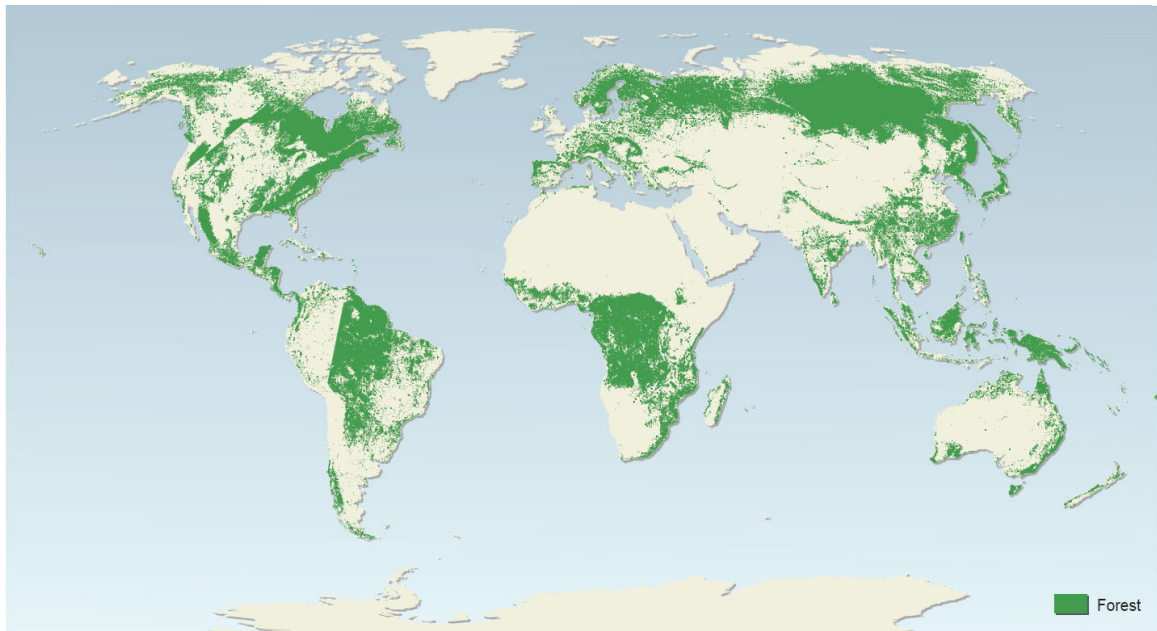

7  
 8  
 9 **Urban, Dryland, and Polar Systems** [Note: Figure above to include legend with MA system  
 10 definitions]  
 11

- 12 • *Urban systems* are built environments with a high human density. For mapping purposes, the  
 13 MA uses known human settlements with a population of 5,000 or more, with boundaries  
 14 delineated by observing persistent night-time lights or by inferring areal extent in the cases  
 15 where such observations are absent. The world's urban population increased from about 200  
 16 million in 1900 to 2.9 billion in 2000, and the number of cities with populations in excess of  
 17 1 million increased from 17 in 1900 to 388 in 2000 (C27.ES).
- 18 • *Dryland systems* are lands where plant production is limited by water availability; the  
 19 dominant human uses are large mammal herbivory, including livestock grazing, and  
 20 cultivation. The map shows drylands as defined by the U.N. Convention to Combat  
 21 Desertification, namely lands where annual precipitation is less than two thirds of potential  
 22 evapotranspiration—from dry subhumid areas (ratio ranges 0.50–0.65) through semiarid,  
 23 arid, and hyperarid (ratio <0.05), but excluding polar areas. Drylands include cultivated  
 24 lands, scrublands, shrublands, grasslands, savannas, semi-deserts, and true deserts. Dryland  
 25 systems cover about 41% of Earth's land surface and are inhabited by more than 2 billion  
 26 people (about one third of the total population) (C22.ES). Croplands cover approximately  
 27 25% of drylands (C22 Table 22.2), and dryland rangelands support approximately 50% of  
 28 the world's livestock (C22.4.2). The current socioeconomic condition of people in dryland  
 29 systems, of which about 90% are in developing countries, is worse than in other areas.  
 30 Freshwater availability in drylands is projected to be further reduced from the current  
 31 average of 1,300 cubic meters per person per year in 2000, which is already below the  
 32 threshold of 2,000 cubic meters required for minimum human well-being and sustainable  
 33 development (C22.ES). Approximately 10–20% of the world's drylands are degraded  
 34 (*medium certainty*) (C22.ES).
- 35 • *Polar systems* are high-latitude systems frozen for most of the year, including ice caps, areas  
 36 underlain by permafrost, tundra, polar deserts, and polar coastal areas. Polar systems do not  
 37 include high-altitude cold systems in low latitudes. Temperature in polar systems is on  
 38 average warmer now than at any time in the last 400 years, resulting in widespread thaw of

1 permafrost and reduction of sea ice (C25.ES). Most changes in feedback processes that occur  
2 in polar regions magnify trace gas-induced global warming trends and reduce the capacity of  
3 polar regions to act as a cooling system for Earth (C25.ES). Tundra constitutes the largest  
4 natural wetland in the world (C25.1.1).

5

6 **Forest Systems** [Note: Figure above to include legend with MA system definitions]

7 • *Forest systems* are lands dominated by trees; they are often used for timber, fuelwood, and  
8 non-timber forest products. The map shows areas with a canopy cover of at least 40% by  
9 woody plants taller than 5 meters. Forests include temporarily cut-over forests and  
10 plantations but exclude orchards and agroforests where the main products are food crops.  
11 The global area of forest systems has been reduced by one half over the past three centuries.  
12 Forests have effectively disappeared in 25 countries, and another 29 have lost more than  
13 90% of their forest cover (C21.ES). Forest systems are associated with the regulation of 57%  
14 of total water runoff. About 4.6 billion people depend for all or some of their water on  
15 supplies from forest systems (C7 Table 7.2). From 1990 to 2000, the global area of  
16 temperate forest increased by almost 3 million hectares per year, while deforestation in the  
17 tropics occurred at an average rate exceeding 12 million hectares per year over the past two  
18 decades (C.SDM).

19

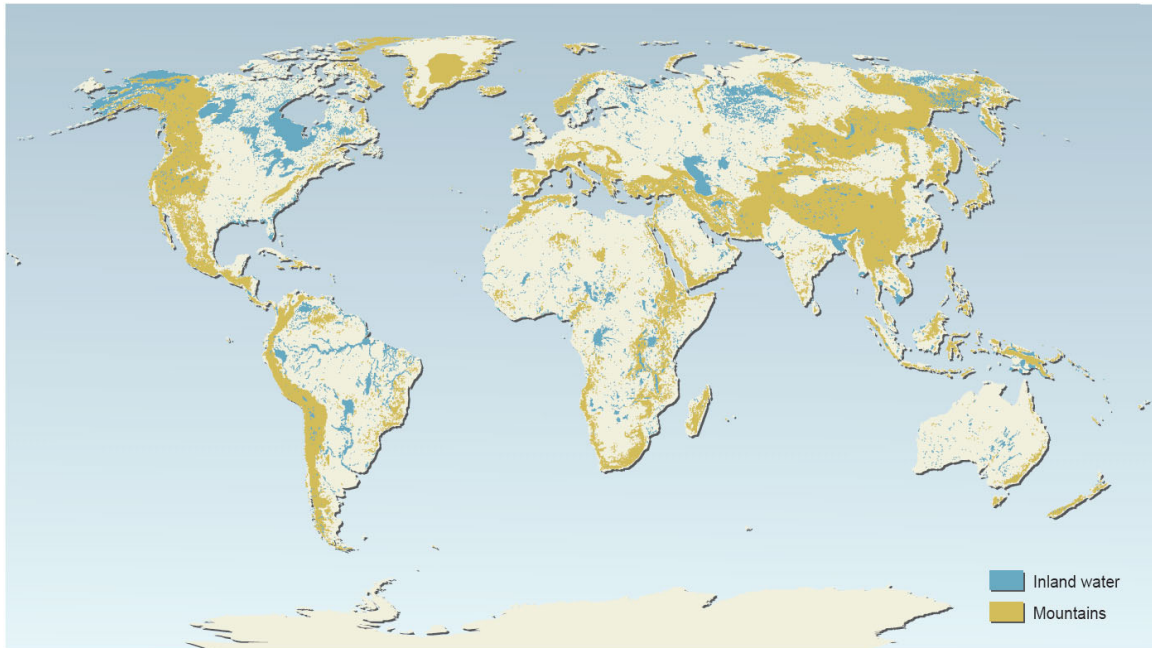

20 **Cultivated Systems**

21

22 • *Cultivated systems* are lands dominated by domesticated species and used for and  
23 substantially changed by crop, agroforestry, or aquaculture production. The map shows areas  
24 in which at least 30% by area of the landscape comes under cultivation in any particular  
25 year. Cultivated systems, including croplands, shifting cultivation, confined livestock  
26 production, and freshwater aquaculture, cover approximately 24% of total land area. In the  
27 last two decades, the major areas of cropland expansion were located in Southeast Asia, parts  
28 of South Asia, the Great Lakes region of eastern Africa, the Amazon Basin, and the U.S.  
29 Great Plains. The major decreases of cropland occurred in the southeastern United States,  
30 eastern China, and parts of Brazil and Argentina (C26.1.1). Most of the increase in food  
31 demand of the past 50 years has been met by intensification of crop, livestock, and  
32 aquaculture systems rather than expansion of production area. In developing countries, over  
33 the period 1961–99 expansion of harvested land contributed only 29% to growth in crop  
34 production, although in sub-Saharan Africa expansion accounted for two thirds of growth in

1 production (C26.1.1). Increased yields of crop production systems have reduced the pressure  
2 to convert natural ecosystems into cropland, but intensification has increased pressure on  
3 inland water ecosystems, generally reduced biodiversity within agricultural landscapes, and  
4 it requires higher energy inputs in the form of mechanization and the production of chemical  
5 fertilizers. Cultivated systems provide only 16% of global runoff, although their close  
6 proximity to humans means that about 5 billion people depend for all or some of their water  
7 on supplies from cultivated systems (C7 Table 7.2). Such proximity is associated with  
8 nutrient and industrial water pollution.

9  
10  
11 ***Inland Water and Mountain Systems*** [Note: Figure above to include legend with MA system  
12 definitions]

- 13
- 14 • *Inland water systems* are permanent water bodies inland from the coastal zone and areas  
15 whose properties and use are dominated by the permanent, seasonal, or intermittent  
16 occurrence of flooded conditions. Inland waters include rivers, lakes, floodplains, reservoirs,  
17 wetlands, and inland saline systems. (Note that the wetlands definition used by the Ramsar  
18 Convention includes the MA inland water and coastal system categories.) The biodiversity  
19 of inland waters appears to be in a worse condition than that of any other system, driven by  
20 declines in both the area of wetlands and the water quality in inland waters (C4 and C20). It  
21 is *speculated* that 50% of inland water area (excluding large lakes) has been lost globally  
22 (C20.ES). Dams and other infrastructure fragment 60% of the large river systems in the  
23 world (C20.4.2).
  - 24 • *Mountain systems* are steep and high lands. The map is based on elevation and, at lower  
25 elevations, a combination of elevation, slope, and local topography. Some 20% (or 1.2  
26 billion) of the world's people live in mountains or at their edges, and half of humankind  
27 depends, directly or indirectly, on mountain resources (largely water) (C24.ES). Nearly all—  
28 90%—of the 1.2 billion people in mountains live in countries with developing or transition  
29 economies. In these countries, 7% of the total mountain area is currently classified as  
30 cropland, and people are often highly dependent on local agriculture or livestock production  
31 (C24.3.2). About 4 billion people depend for all or some of their water on supplies from  
32 mountain systems. Some 90 million mountain people—almost all those living above 2,500  
33 meters—live in poverty and are considered especially vulnerable to food insecurity  
34 (C24.1.4).

1 **Table 1.1. Comparative Table of Systems as Reported by the Millennium Ecosystem**  
2 **Assessment (C.SDM).** Note that as described in Box 1.1, these systems often overlap.  
3 Statistics for different systems can therefore be compared but cannot be totaled across  
4 systems, as this will result in partial double-counting.

1 **Figure 1.5. Global Trends in the Creation of Reactive Nitrogen on Earth by Human**  
 2 **Activity, with Projection to 2050** (teragrams nitrogen per year). Most of the reactive  
 3 nitrogen produced by humans comes from manufacturing nitrogen for synthetic fertilizer  
 4 and industrial use. Reactive nitrogen is also created as a by-product of fossil fuel  
 5 combustion and by some (nitrogen-fixing) crops and trees in agroecosystems. The range  
 6 of the natural rate of bacterial nitrogen fixation in natural terrestrial ecosystems  
 7 (excluding fixation in agroecosystems) is shown for comparison. Human activity now  
 8 produces approximately as much reactive nitrogen as natural processes do on the  
 9 continents (R9 Fig 9.1). (Note: the 2050 projection is included in the original study and is  
 10 not based on MA Scenarios.)  
 11

12

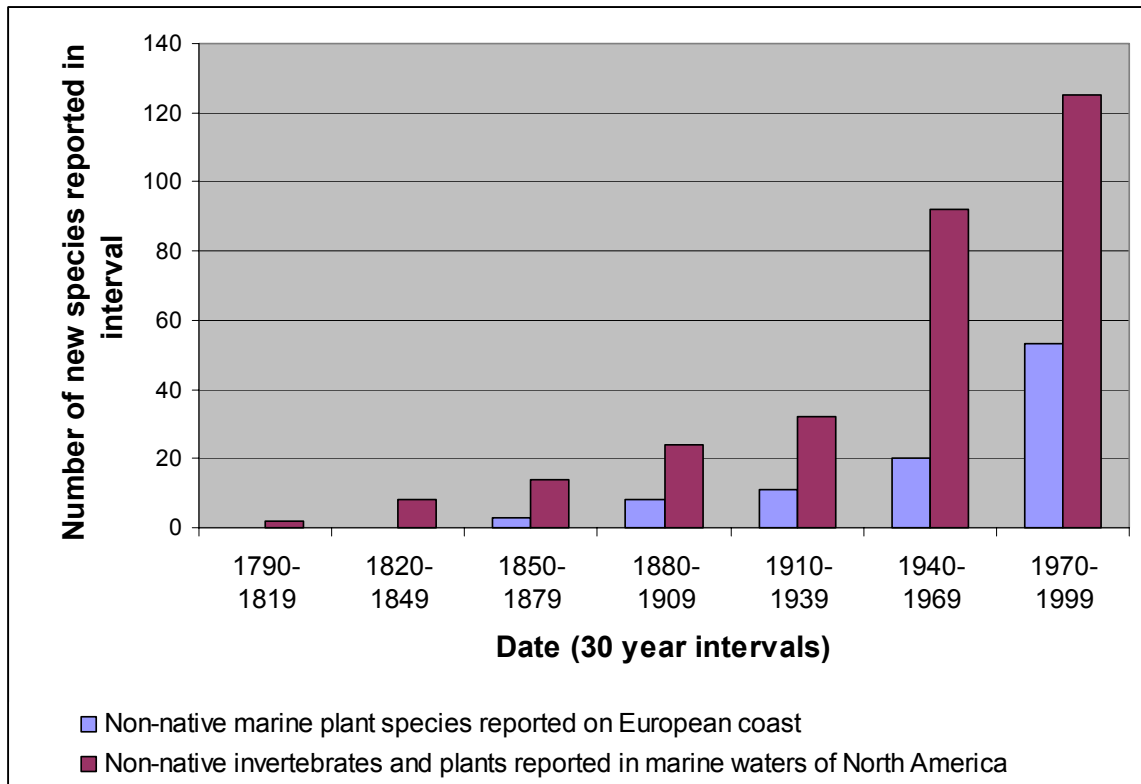

1 **Figure 1.6. Estimated Total Reactive Nitrogen Deposition from the Atmosphere**  
2 **(Wet and Dry) in 1860, early 1990s, and Projected for 2050** (milligrams of nitrogen  
3 per square meter per year). Atmospheric deposition currently accounts for roughly 12%  
4 of the reactive nitrogen entering terrestrial and coastal marine ecosystems globally,  
5 although in some regions, atmospheric deposition accounts for a higher percentage (about  
6 33% in the United States) (R9 Figure 9.2). (Note: the projection was included in the  
7 original study and is not based on MA Scenarios.)  
8

9

1 **Figure 1.7. Growth in Number of Marine Species Introductions.** Number of new  
2 records of established non-native invertebrate and algae species reported in marine waters  
3 of North America shown by date of first record and number of new records of non-native  
4 marine plant species reported on the European coast by date of first record.

5  
6

1 **Figure 1.8. Species Extinction Rates** (Adapted from C4 Fig 4.22). “Fossil Record”  
 2 refers to average extinction rates as estimated from the fossil record. “Past Century—  
 3 Known Species” refers to extinction rates calculated from known extinctions of species  
 4 (lower estimate) or known extinctions plus “possibly extinct” species (upper bound). A  
 5 species is considered to be “possibly extinct” if it is believed by experts to be extinct but  
 6 extensive surveys have not yet been undertaken to confirm its disappearance. “Projected”  
 7 extinctions are model-derived estimates using a variety of techniques, including species-  
 8 area models, rates at which species are shifting to increasingly more threatened  
 9 categories, extinction probabilities associated with the IUCN categories of threat, impacts  
 10 of projected habitat loss on species currently threatened with habitat loss, and correlation  
 11 of species loss with energy consumption. The time frame and species groups involved  
 12 differ among the “projected” estimates, but in general refer to either future loss of species  
 13 based on the level of threat that exists today or current and future loss of species as a  
 14 result of habitat changes taking place over the period of roughly 1970 to 2050. Estimates  
 15 based on the fossil record are *low certainty*; lower-bound estimates for known extinctions  
 16 are *high certainty* and upper-bound estimates are *medium certainty*; lower-bound  
 17 estimates for projected extinctions are *low certainty* and upper bound estimates are  
 18 *speculative*.

## 2. How have ecosystem services and their uses changed?

Ecosystem services are the benefits provided by ecosystems. These include provisioning services such as food, water, timber, fiber, and genetic resources; regulating services such as the regulation of climate, floods, disease, and water quality as well as waste treatment; cultural services such as recreation, aesthetic enjoyment, and spiritual fulfillment; and supporting services such as soil formation, pollination, and nutrient cycling. (See Box 2.1.)

**Human use of all ecosystem services is growing rapidly. Approximately 60% (15 out of 24) of the ecosystem services evaluated in this assessment (including 70% of regulating and cultural services) are being degraded or used unsustainably.** (See Table 2.1.) Of 24 provisioning, cultural, and regulating ecosystem services for which sufficient information was available, the use of 20 continues to increase. The use of one service, capture fisheries, is now declining as a result of a decline in the quantity of fish, which in turn is due to excessive capture of fish in past decades. Two other services (fuelwood and fiber) show mixed patterns. The use of some types of fiber is increasing and others decreasing; in the case of fuelwood, there is evidence of a recent peak in use.

Humans have enhanced production of three ecosystem services – crops, livestock, and aquaculture – through expansion of the area devoted to their production or through technological inputs. Recently, the service of carbon sequestration has been enhanced globally, due in part to the re-growth of forests in temperate regions, although previously deforestation had been a net source of carbon emissions. Half of provisioning services (6 of 11) and nearly 70% (9 of 13) of regulating and cultural services are being degraded or used unsustainably.

▪ **Provisioning Services: The quantity of provisioning ecosystem services such as food, water, and timber used by humans increased rapidly, often more rapidly than population growth although generally slower than economic growth, during the second half of the twentieth century. And it continues to grow. In a number of cases, provisioning services are being used at unsustainable rates.** The growing human use has been made possible by a combination of substantial increases in the absolute amount of some services produced by ecosystems and an increase in the fraction used by humans. World population doubled between 1960 and 2000, from 3 billion to 6 billion people, and the global economy increased more than sixfold. During this time, food production increased by roughly two-and-a-half times (a 160% increase in food production between 1961 and 2003), water use doubled, wood harvests for pulp and paper tripled, and timber production increased by nearly 60% (C9.ES, C9.2.2, S7, C7.2.3, C8.1). (Food production increased fourfold in developing countries over this period.)

The sustainability of the use of provisioning services differs in different locations. However, the use of several provisioning services is unsustainable even in the global aggregate. The current level of use of capture fisheries (marine and freshwater) is not sustainable, and many fisheries have already collapsed. Currently, one quarter of important commercial fish stocks are overexploited or significantly depleted (*high certainty*) (C8.2.2). From 5% to possibly 25% of global freshwater use exceeds long-term accessible supplies and is maintained only through engineered water transfers or

1 the overdraft of groundwater supplies (*low to medium certainty*) (C7.ES). Between  
2 15% and 35% of irrigation withdrawals exceed supply rates and are therefore  
3 unsustainable (*low to medium certainty*) (C7.2.2). Current agricultural practices are  
4 also unsustainable in some regions due to their reliance on unsustainable sources of  
5 water, harmful impacts caused by excessive nutrient or pesticide use, salinization,  
6 nutrient depletion, and rates of soil loss that exceed rates of soil formation.

7 ▪ **Regulating Services: Humans have substantially altered regulating services such**  
8 **as disease and climate regulation by modifying the ecosystem providing the**  
9 **service and, in the case of waste processing services, by exceeding the capabilities**  
10 **of ecosystems to provide the service.** Most changes to regulating services are  
11 inadvertent results of actions taken to enhance the supply of provisioning services.  
12 Humans have substantially modified the climate regulation service of ecosystems—  
13 first by greatly increasing the amount of carbon dioxide and other greenhouse gases  
14 such as methane and nitrous oxide in the atmosphere and more recently by increasing  
15 the sequestration of carbon dioxide (although ecosystems remain a net source of  
16 methane and nitrous oxide). Modifications of ecosystems have altered patterns of  
17 disease by increasing or decreasing habitat for certain diseases or their vectors (such  
18 as dams and irrigation canals that provide habitat for schistosomiasis) or by bringing  
19 human populations into closer contact with various disease organisms. Changes to  
20 ecosystems have contributed to a significant rise in the number of floods and major  
21 wildfires on all continents since the 1940s. Ecosystems serve an important role in  
22 detoxifying wastes introduced into the environment, but there are intrinsic limits to  
23 that waste processing capability. For example, aquatic ecosystems “cleanse” on  
24 average 80% of their global incident nitrogen loading, but this intrinsic self-  
25 purification capacity varies widely and is being reduced by the loss of wetlands  
26 (C7.2.5).

27 ▪ **Cultural Services: Although the use of cultural services has continued to grow,**  
28 **the capability of ecosystems to provide cultural benefits has been significantly**  
29 **diminished in the past century** (C17). Human cultures are strongly influenced by  
30 ecosystems, and ecosystem change can have a significant impact on cultural identity  
31 and social stability. Human cultures, knowledge systems, religions, heritage values,  
32 social interactions, and the linked amenity services (such as aesthetic enjoyment,  
33 recreation, artistic and spiritual fulfillment, and intellectual development) have always  
34 been influenced and shaped by the nature of the ecosystem and ecosystem conditions.  
35 Many of these benefits are being degraded, either through changes to ecosystems (a  
36 recent rapid decline in the numbers of sacred groves and other such protected areas,  
37 for example) or through societal changes (such as the loss of languages or of  
38 traditional knowledge) that reduce people’s recognition or appreciation of those  
39 cultural benefits. Rapid loss of culturally valued ecosystems and landscapes can  
40 contribute to social disruptions and societal marginalization. And there has been a  
41 decline in the quantity and quality of aesthetically pleasing natural landscapes.

42 **Global gains in the supply of food, water, timber, and other provisioning services**  
43 **were often achieved in the past century despite local resource depletion and local**  
44 **restrictions on resource use by shifting production and harvest to new**  
45 **underexploited regions, sometimes considerable distances away. These options are**  
46 **diminishing.** This trend is most distinct in the case of marine fisheries. (See Figure 2.1.)  
47 As individual stocks have been depleted, fishing pressure has shifted to less exploited

1 stocks ( C18.3.1). Industrial fishing fleets have also shifted to fishing further offshore and  
2 in deeper water to meet global demand (C18.ES). (See Figure 2.2.) A variety of drivers  
3 related to market demand, supply, and government policies have influenced patterns of  
4 timber harvest. For example, international trade in forest products increases when a  
5 nation’s forests no longer can meet demand or when policies have been established to  
6 restrict or ban timber harvest.

7 **Although human demand for ecosystem services continues to grow in the aggregate,**  
8 **the demand for particular services in specific regions is declining as substitutes are**  
9 **developed.** For example, kerosene, electricity, and other energy sources are increasingly  
10 being substituted for fuelwood (still the primary source of energy for heating and cooking  
11 for some 2.6 billion people) (C9-ES). The substitution of a variety of other materials for  
12 wood (such as vinyl, plastics, and metal) has contributed to relatively slow growth in  
13 global timber consumption in recent years (C9.2.1). While the use of substitutes can  
14 reduce pressure on specific ecosystem services, this may not always have positive net  
15 environmental benefits. Substitution of fuelwood by fossil fuels, for example, reduces  
16 pressure on forests and lowers indoor air pollution, but it may increase net greenhouse gas  
17 emissions. Substitutes are also often costlier to provide than the original ecosystem  
18 services.

19 **Both the supply and the resilience of ecosystem services are affected by changes in**  
20 **biodiversity.** Biodiversity is the variability among living organisms and the ecological  
21 complexes of which they are part. When a species is lost from a particular location (even  
22 if it does not go extinct globally) or introduced to a new location, the various ecosystem  
23 services associated with that species are changed. More generally, when a habitat is  
24 converted, an array of ecosystem services associated with the species present in that  
25 location is changed, often with direct and immediate impacts on people (S10). Changes in  
26 biodiversity also have numerous indirect impacts on ecosystem services over longer time  
27 periods, including influencing the capacity of ecosystems to adjust to changing  
28 environments (*medium certainty*), causing disproportionately large and sometimes  
29 irreversible changes in ecosystem processes, influencing the potential for infectious  
30 disease transmission, and, in agricultural systems, influencing the risk of crop failure in a  
31 variable environment and altering the potential impacts of pests and pathogens (*high to*  
32 *medium certainty*) (C11.ES, C14.ES).

33 **The modification of an ecosystem to alter one ecosystem service (to increase food or**  
34 **timber production, for instance) generally results in changes to other ecosystem**  
35 **services as well** (CWG; SG7). Trade-offs among ecosystem services are commonplace.  
36 (See Table 2.2.) For example, actions to increase food production often involve one or  
37 more of the following: increased water use, degraded water quality, reduced biodiversity,  
38 reduced forest cover, loss of forest products, or release of greenhouse gases. Frequent  
39 cultivation, irrigated rice production, livestock production, and burning of cleared areas  
40 and crop residues now release 1,600±800 million tons of carbon per year in CO<sub>2</sub>  
41 (C26.ES). Cultivation, irrigated rice production, and livestock production release  
42 between 106 and 201 million tons of carbon per year in methane (C13 Table 26.1). About  
43 70% of anthropogenic nitrous oxide gas emissions are attributable to agriculture, mostly  
44 from land conversion and nitrogen fertilizer use (C26.ES). Similarly, the conversion of  
45 forest to agriculture can significantly change flood frequency and magnitude, although the  
46 amount and direction of this impact is highly dependent on the characteristics of the local  
47 ecosystem and the nature of the land cover change (C21.5.2).

1 Many trade-offs associated with ecosystem services are expressed in areas remote from  
2 the site of degradation. For example, conversion of forests to agriculture can affect water  
3 quality and flood frequency downstream of where the ecosystem change occurred. And  
4 increased application of nitrogen fertilizers to croplands can have negative impacts on  
5 coastal water quality. These trade-offs are rarely taken fully into account in decision-  
6 making, partly due to the sectoral nature of planning and partly because some of the  
7 effects are also displaced in time (such as long-term climate impacts).

8 **The net benefits gained through actions to increase the productivity or harvest of**  
9 **ecosystem services have been less than initially believed after taking into account**  
10 **negative trade-offs.** The benefits of resource management actions have traditionally been  
11 evaluated only from the standpoint of the service targeted by the management  
12 intervention. However, management interventions to increase any particular service  
13 almost always result in costs to other services. Negative trade-offs are commonly found  
14 between individual provisioning services and between provisioning services and the  
15 combined regulating, cultural, and supporting services and biodiversity. Taking the costs  
16 of these negative trade-offs into account reduces the apparent benefits of the various  
17 management interventions. For example:

- 18
- 19 ▪ Expansion of commercial shrimp farming has had serious impacts on ecosystems,  
20 including loss of vegetation, deterioration of water quality, decline of capture  
21 fisheries, and loss of biodiversity (R6, C19).  
22
- 23 ▪ Expansion of livestock production around the world has often led to overgrazing and  
24 dryland degradation, rangeland fragmentation, loss of wildlife habitat, dust formation,  
25 bush encroachment, deforestation, nutrient overload through disposal of manure, and  
26 greenhouse gas emissions (R6-ES).
- 27 ▪ Poorly designed and executed agricultural policies led to an irreversible change in the  
28 Aral Sea ecosystem. By 1998, the Aral Sea had lost more than 60% of its area and  
29 approximately 80% of its volume, and ecosystem-related problems in the region now  
30 include excessive salt content of major rivers, contamination of agricultural products  
31 with agrochemicals, high levels of turbidity in major water sources, high levels of  
32 pesticides and phenols in surface waters, loss of soil fertility, extinctions of species,  
33 and destruction of commercial fisheries (R6-Box 6.9).  
34
- 35 ▪ Forested riparian wetlands adjacent to the Mississippi river in the United States had  
36 the capacity to store about 60 days of river discharge. With the removal of the  
37 wetlands through canalization, leveeing, and draining, the remaining wetlands have a  
38 storage capacity of less than 12 days discharge, an 80% reduction in flood storage  
39 capacity (C16.1.1).

40 **However, positive synergies can be achieved as well when actions to conserve or**  
41 **enhance a particular component of an ecosystem or its services benefit other services**  
42 **or stakeholders.** Agroforestry can meet human needs for food and fuel, restore soils, and  
43 contribute to biodiversity conservation. Intercropping can increase yields, increase  
44 biocontrol, reduce soil erosion, and reduce weed invasion in fields. Urban parks and other  
45 urban green spaces provide spiritual, aesthetic, educational, and recreational benefits as  
46 well as such services such as water purification, wildlife habitat, waste management, and  
47 carbon sequestration. Protection of natural forests for biodiversity conservation can also

1 reduce carbon emissions and protect water supplies. Protection of wetlands can contribute  
2 to flood control and also help to remove pollutants such as phosphorus and nitrogen from  
3 the water. For example, it is estimated that the nitrogen load from the heavily polluted  
4 Illinois River basin to the Mississippi River could be cut in half by converting 7% of the  
5 basin back to wetlands (R9.4.5). Positive synergies often exist among regulating, cultural,  
6 and supporting services and with biodiversity conservation.

## Box 2.1. Ecosystem Services

Ecosystem services are the benefits people obtain from ecosystems. These include provisioning, regulating, and cultural services that directly affect people and the supporting services needed to maintain other services (CF-2). Many of the services listed here are highly interlinked. (Primary production, photosynthesis, nutrient cycling, and water cycling, for example, all involve different aspects of the same biological processes.)

**Provisioning Services.** These are the products obtained from ecosystems, including:

*Food.* This includes the vast range of food products derived from plants, animals, and microbes.

*Fiber.* Materials included here are wood, jute, cotton, hemp, silk, and wool.

*Fuel.* Wood, dung, and other biological materials serve as sources of energy.

*Genetic resources.* This includes the genes and genetic information used for animal and plant breeding and biotechnology.

*Biochemicals, natural medicines, and pharmaceuticals.* Many medicines, biocides, food additives such as alginates, and biological materials are derived from ecosystems.

*Ornamental resources.* Animal and plant products, such as skins, shells, and flowers, are used as ornaments, and whole plants are used for landscaping and ornaments.

*Fresh water.* People obtain fresh water from ecosystems and thus the supply of fresh water can be considered a provisioning service. Fresh water in rivers is also a source of energy. Because water is required for other life to exist, however, it could also be considered a supporting service.

**Regulating Services.** These are the benefits obtained from the regulation of ecosystem processes, including:

*Air quality regulation.* Ecosystems both contribute chemicals to and extract chemicals from the atmosphere, influencing many aspects of air quality.

*Climate regulation.* Ecosystems influence climate both locally and globally. At a local scale, for example, changes in land cover can affect both temperature and precipitation. At the global scale, ecosystems play an important role in climate by either sequestering or emitting greenhouse gases.

*Water regulation.* The timing and magnitude of runoff, flooding, and aquifer recharge can be strongly influenced by changes in land cover, including, in particular, alterations that change the water storage potential of the system, such as the conversion of wetlands or the replacement of forests with croplands or croplands with urban areas.

*Erosion regulation.* Vegetative cover plays an important role in soil retention and the prevention of landslides.

*Water purification and waste treatment.* Ecosystems can be a source of impurities (for instance, in fresh water) but also can help filter out and decompose organic wastes introduced into inland waters and coastal and marine ecosystems and can assimilate and detoxify compounds through soil and subsoil processes.

*Disease regulation.* Changes in ecosystems can directly change the abundance of human pathogens, such as cholera, and can alter the abundance of disease vectors, such as mosquitoes.

*Pest regulation.* Ecosystem changes affect the prevalence of crop and livestock pests and diseases.

*Pollination.* Ecosystem changes affect the distribution, abundance, and effectiveness of pollinators.

*Natural hazard regulation.* The presence of coastal ecosystems such as mangroves and coral reefs can reduce the damage caused by hurricanes or large waves.

**Cultural Services.** These are the nonmaterial benefits people obtain from ecosystems through spiritual enrichment, cognitive development, reflection, recreation, and aesthetic experiences, including:

*Cultural diversity.* The diversity of ecosystems is one factor influencing the diversity of cultures.

1 *Spiritual and religious values.* Many religions attach spiritual and religious values to ecosystems  
2 or their components.

3 *Knowledge systems* (traditional and formal). Ecosystems influence the types of knowledge  
4 systems developed by different cultures.

5 *Educational values.* Ecosystems and their components and processes provide the basis for both  
6 formal and informal education in many societies.

7 *Inspiration.* Ecosystems provide a rich source of inspiration for art, folklore, national symbols,  
8 architecture, and advertising.

9 *Aesthetic values.* Many people find beauty or aesthetic value in various aspects of ecosystems, as  
10 reflected in the support for parks, scenic drives, and the selection of housing locations.

11 *Social relations.* Ecosystems influence the types of social relations that are established in  
12 particular cultures. Fishing societies, for example, differ in many respects in their social  
13 relations from nomadic herding or agricultural societies.

14 *Sense of place.* Many people value the “sense of place” that is associated with recognized features  
15 of their environment, including aspects of the ecosystem.

16 *Cultural heritage values.* Many societies place high value on the maintenance of either  
17 historically important landscapes (“cultural landscapes”) or culturally significant species.

18 *Recreation and ecotourism.* People often choose where to spend their leisure time based in part on  
19 the characteristics of the natural or cultivated landscapes in a particular area.

20

21 ***Supporting Services.*** Supporting services are those that are necessary for the production of all  
22 other ecosystem services. They differ from provisioning, regulating, and cultural services in that  
23 their impacts on people are often indirect or occur over a very long time, whereas changes in the  
24 other categories have relatively direct and short-term impacts on people. (Some services, like  
25 erosion regulation, can be categorized as both a supporting and a regulating service, depending on  
26 the time scale and immediacy of their impact on people.) These services include:

27 *Soil Formation.* Because many provisioning services depend on soil fertility, the rate of soil  
28 formation influences human well-being in many ways.

29 *Photosynthesis.* Photosynthesis produces oxygen necessary for most living organisms.

30 *Primary production.* The assimilation or accumulation of energy and nutrients by organisms.

31 *Nutrient cycling.* Approximately 20 nutrients essential for life, including nitrogen and phosphorus,  
32 cycle through ecosystems and are maintained at different concentrations in different parts of  
33 ecosystems.

34 *Water cycling.* Water cycles through ecosystems and is essential for living organisms.

35

**Table 2.1. Trends in the Human Use of Ecosystem Services and Enhancement or Degradation of the Service Around the Year 2000**

**Legend**

= Increasing (for Human Use column) or enhanced (for Enhanced or Degraded column)

= Decreasing (for Human Use column) or degraded (for Enhanced or Degraded column)

**+/-** = Mixed (trend increases and decreases over past 50 years or some components/regions increase while others decrease)

**\*** = Low to medium certainty. All other trends are medium to high certainty.

**NA** = Not assessed within the MA. In some cases, the service was not addressed at all in the MA (such as ornamental resources), while in other cases the service was included but the information and data available did not allow an assessment of the pattern of human use of the service or the status of the service.

**†** = The categories of “Human Benefit” and “Enhanced or Degraded” do not apply for supporting services since, by definition, these services are not directly used by people. (Their costs or benefits would be double-counted if the indirect effects were included). Changes in supporting services influence the supply of provisioning, cultural, or regulating services that are then used by people and may be enhanced or degraded.

Service	Sub-category	Human Use <sup>a</sup>	Enhanced or Degraded <sup>b</sup>	Notes	MA Chapter
<b>Provisioning Services</b>					
Food	Crops	↑	↑	Significant increase in area devoted to agriculture and in production per unit area.	C8.2
	Livestock	↑	↑	Significant increase in area devoted to livestock and increase in production per unit area.	C8.2
	Capture Fisheries	↓	↓	Marine fish harvest increased until the late 1980s and has been declining since then. Currently, one quarter of marine fish stocks are overexploited or significantly depleted. Freshwater capture fisheries have also declined. Human use of capture fisheries has declined because of the reduced supply, not because of reduced demand.	C18, C8.2.2
	Aquaculture	↑	↑	Aquaculture has become a globally significant source of food in the last 50 years and, in 2000, contributed 27% of total fish production.	C8 Table 8.4
	Wild plant and animal food products	NA	↓	Provision of these food sources is generally declining as natural habitats worldwide are under increasing pressure and as wild populations are exploited for food at unsustainable levels.	8.3.1
Fiber	Timber	↑	+/-	Global timber production has increased by 60% in the last four decades. Plantations provide an increasing volume of harvested roundwood, amounting to 35% of the global harvest in 2000. Roughly 40% of forest area has been lost during the industrial era, and forests continue to be lost in many regions (thus the service is degraded in those regions), although forest is now recovering in some temperate countries and thus this service has been enhanced (from this lower baseline) in these regions in recent decades.	C9.ES, C21.1
	Cotton, hemp, silk	+/-	+/-	Cotton and silk production have doubled and tripled respectively in the last four decades. Production of other agricultural fibers has declined.	C9.ES
	Wood fuel	+/-	↓	Global consumption of fuelwood appears to have peaked in the 1990s and is now believed to be slowly declining.	C9.ES

Service	Sub-category	Human Use <sup>a</sup>	Enhanced or Degraded <sup>b</sup>	Notes	MA Chapter
Genetic resources				Use of genetic resources grows in both traditional industries (e.g., crop breeding) and in connection with new biotechnologies. Genetic resources have been lost through the loss of traditional cultivars of crop species and through species extinctions.	C26.2.1
Biochemicals, natural medicines, and pharmaceuticals				Demand for biochemicals and new pharmaceuticals is growing, but new synthetic technologies compete with natural products to meet the supply. Historically, use of natural products has been cyclical. For many other natural products (cosmetics, personal care, bioremediation, biomonitoring, ecological restoration), use is growing.	C10
Ornamental resources		NA	NA		
Fresh water				Human modification to ecosystems (e.g., reservoir creation) have made more fresh water available to people but have not changed the actual quantity. The timing of availability of water has been altered by the use of infrastructure, such as dams, although vegetation changes have also had an impact on the seasonal flow of water in river systems. From 5% to possibly 25% of global fresh water use exceeds long-term accessible supplies and requires supplies either through engineered water transfers or overdraft of groundwater supplies. Water flowing in rivers provides a source of energy that is exploited through hydropower. The construction of dams has not changed the amount of energy, but it has made the energy more available to people. The installed hydroelectric capacity doubled between 1960 and 2000. The service provided by ecosystems, however, has neither been enhanced nor degraded.	C7

<b>Regulating Services</b>					
Air quality regulation				The ability of the atmosphere to cleanse itself of pollutants has declined slightly since pre-industrial times but likely not by more than 10%. The net contribution of ecosystems to this change is not known. Ecosystems are also a sink for tropospheric ozone, ammonia, NO <sub>x</sub> , SO <sub>2</sub> , particulates, and CH <sub>4</sub> , but changes in these sinks were not assessed.	C13.ES
Climate regulation	Global			Terrestrial ecosystems were on average a net source of CO <sub>2</sub> during the nineteenth and early twentieth century, and became a net sink sometime around the middle of the last century. The biophysical effect of historical land cover changes (1750 to present) is net cooling on a global scale due to increased albedo, partially offsetting the warming effect of associated CO <sub>2</sub> emissions from land cover change over much of that period.	C13.ES
	Regional and local			Changes in land cover have affected regional and local climates both positively and negatively, but there is a preponderance of negative impacts. For example, tropical deforestation and desertification have tended to reduce local rainfall.	C13.3, C11.3

Service	Sub-category	Human Use <sup>a</sup>	Enhanced or Degraded <sup>b</sup>	Notes	MA Chapter
Water regulation			+/-	The effect of ecosystem change on the timing and magnitude of runoff, flooding, and aquifer recharge depends on the specific change and the specific ecosystem.	C7.4.4
Erosion regulation				Land use and crop/soil management practices have exacerbated soil degradation and erosion, although appropriate soil conservation practices are increasingly being adopted.	C26
Water purification and waste treatment				Globally, water quality is declining, although in most industrial countries pathogen and organic pollution of surface waters has decreased over the last 20 years. Both pesticide contamination and nitrate concentration have grown rapidly in the last 30 years.	C7.2.5
Disease regulation			+/-	Ecosystem modifications associated with development have often increased the local incidence of infectious diseases, although major changes in habitats can both increase or decrease the risk of particular infectious diseases.	C14
Pest regulation				In many agricultural areas, pest control provided by natural enemies has been replaced by the use of pesticides. Such pesticide use has itself degraded the capacity of agroecosystems to provide pest control. In other systems, pest control provided by natural enemies is being used and enhanced through integrated pest management.	C11.3
Pollination				There is established but incomplete evidence of a global decline in the abundance of pollinators. Pollinator declines have been reported in at least one region or country on every continent except for Antarctica, which has no pollinators. Declines in abundance of pollinators have rarely resulted in complete failure to produce seed or fruit, but more frequently resulted in fewer seeds or in fruit of reduced viability or quantity. Losses in populations of specialized pollinators have directly affected the reproductive ability of some rare plants.	C11 Box 11.2
Natural hazard regulation				People are increasingly occupying regions and localities that are exposed to extreme events, thereby exacerbating human vulnerability to natural hazards. This trend, along with the decline in the capacity of ecosystems to buffer from extreme events, has led to continuing high loss of life globally and rapidly rising economic losses from natural disasters.	C16

<b>Cultural Services</b>					
Cultural diversity		NA	NA		
Spiritual and religious values				There has been a decline in the numbers of sacred groves and other such protected areas. The loss of particular ecosystem attributes (sacred species or sacred forests), combined with social and economic changes, can sometimes weaken the spiritual benefits people obtain from ecosystems. On the other hand, under some circumstances (e.g., where ecosystem attributes are causing significant threats to people), the loss of some attributes may enhance spiritual appreciation for what remains.	C17.2.3

Service	Sub-category	Human Use <sup>a</sup>	Enhanced or Degraded <sup>b</sup>	Notes	MA Chapter
Knowledge systems		NA	NA		
Educational values		NA	NA		
Inspiration		NA	NA		
Aesthetic values		↑	↓	The demand for aesthetically pleasing natural landscapes has increased in accordance with increased urbanization. There has been a decline in quantity and quality of areas to meet this demand. A reduction in the availability of and access to natural areas for urban residents may have important detrimental effects on public health and economies.	C17.2.5
Social relations		NA	NA		
Sense of place		NA	NA		
Cultural heritage values		NA	NA		
Recreation and ecotourism		↑	+/-	The demand for recreational use of landscapes is increasing, and areas are increasingly being managed to cater for this use, to reflect changing cultural values and perceptions. However, many naturally occurring features of the landscape (e.g., coral reefs) have been degraded as resources for recreation.	C17.2.6

Supporting Services					
Soil formation		↑	↑		
Photosynthesis		↑	↑		
Primary production		↑	↑	Several global MA systems, including drylands, forest, and cultivated systems, show a trend of NPP increase for the period 1981 to 2000. However, high seasonal and inter-annual variations associated with climate variability occur within this trend on the global scale	C22.2.1
Nutrient cycling		↑	↑	There have been large-scale changes in nutrient cycles in recent decades, mainly due to additional inputs from fertilizers, livestock waste, human wastes, and biomass burning. Inland water and coastal systems have been increasingly affected by eutrophication due to transfer of nutrients from terrestrial to aquatic systems.	C12, S7
Water cycling		↑	↑	Humans have made major changes to water cycles through structural changes to rivers, extraction of water from rivers, and, more recently, climate change.	C7

<sup>a</sup> For provisioning services, human use increases if the human consumption of the service increases (e.g., greater food consumption); for regulating and cultural services, human use increases if the number of people affected by the service increases.

<sup>b</sup> For provisioning services, we define enhancement to mean increased production of the service through changes in area over which the service is provided (e.g., spread of agriculture) or increased production per unit area. We judge the production to be degraded if the current use exceeds sustainable levels. For regulating and supporting services, enhancement refers to a change in the service that leads to greater benefits for people (e.g., the service of disease regulation could be improved by eradication of a vector known to transmit a disease to people). Degradation of a regulating and supporting services means a reduction in the benefits obtained from the service, either through a change in the service (e.g., mangrove loss reducing the storm protection benefits of an ecosystem) or through human pressures on the service exceeding its limits (e.g., excessive pollution exceeding

1 the capability of ecosystems to maintain water quality). For cultural services, enhancement refers to a change in  
2 the ecosystem features that increase the cultural (recreational, aesthetic, spiritual, etc.) benefits provided by the  
3 ecosystem.

1 **Table 2.2. Indicative Ecosystem Service Trade-offs.** The nature and direction of trade-offs among ecosystem services depends significantly on  
 2 the specific management practices used to change the target service and on the ecosystem involved. This table summarizes common directions of  
 3 trade-offs encountered across ecosystem services, although the magnitude (or even direction) of the trade-off may differ from case to case.

- 4 Key: – change in the left column has a negative impact on the service above  
 5 + change in the left column has a positive impact on the service above  
 6 0 the change is neutral or has no effect on the service above  
 7 NA the category is not applicable

Effects of Changes to Ecosystem Services Below on Ecosystem Services to the Right	Provisioning Services			Regulating Services			Cultural Services		Supporting Services	Notes
	Food Production	Water Availability and Quality	Fiber Production	Carbon Sequestration	Disease Reduction	Flood Control	Ecotourism Potential	N Regulation (Avoidance of Eutrophication)		
Increased food production through intensification of agriculture	Intervention target	–	0	–	+/-	0	0	–	–	Agricultural ecosystems reduce exposure to certain diseases but increase the risk of other diseases
Increased food production through expansion of agriculture	Intervention target	–	–	–	+/-	–	–	–	–	
Increased wild fish catch	Intervention target	NA	NA	NA	NA	NA	+/-	+/-	+/-	Increased fish catch can increase ecotourism opportunities (e.g., increased sport fishing opportunities) or decrease them if the levels are unsustainable or if the increased catch reduces populations of predators that attract tourists (e.g. killer whales, seals, sea lions).
Damming rivers to increase water availability	+	Intervention target	–	+/-	–	+/-	+/-	–	–	River modification can reduce flood frequency but increase the risk and magnitude of catastrophic floods. Reservoirs provide recreational opportunities but the recreational opportunities associated with the original river are lost.
Increased timber harvest	–	+/-	Intervention target	–	+/-	+/-	–	0	0	Timber harvest generally reduces availability of wild sources of food.
Draining or filling wetlands to reduce malaria risk	+	–	0	0	Intervention target	–	–	–	–	Filled wetlands are often used for agriculture. Loss of wetlands results in a loss of water cleansing capability, loss of a source of flood control and loss of ecotourism potential.
Establishing a strictly	–	+	–	+	+/-	+	+	+	+	Strictly protected areas may result in the loss of a local source of food supply and fiber production.

protected area to maintain biodiversity and provide recreation										The presence of the protected area protects water supplies and water quality, prevents emissions of greenhouse gases that might have resulted from habitat conversion and increases tourism potential.

### 3. How have ecosystem changes affected human well-being and poverty alleviation?

#### *Relationships between Ecosystem Services and Human Well-being*

**Changes in ecosystem services influence all components of human well-being, including the basic material needs for a good life, health, good social relations, security, and freedom of choice and action (CF3).** (See Box 3.1.) Humans are fully dependent on Earth's ecosystems and the services that they provide, such as food, clean water, disease regulation, climate regulation, spiritual fulfillment, and aesthetic enjoyment. The relationship between ecosystem services and human well-being is mediated by access to manufactured, human, and social capital. Human well-being depends on ecosystem services but also on the supply and quality of social capital, technology, and institutions. These factors mediate the relationship between ecosystem services and human well-being in ways that remain contested and incompletely understood. The relationship between human well-being and ecosystem services is not linear. When an ecosystem service is abundant relative to the demand, a marginal increase in ecosystem services generally contributes only slightly to human well-being (or may even diminish it). But when the service is relatively scarce, a small decrease can substantially reduce human well-being (S.SDM, SG3.4).

**Ecosystem services contribute significantly to global employment and economic activity.** The ecosystem service of food production contributes by far the most to economic activity and employment. In 2000, the market value of food production was \$981 billion, or roughly 3% of global GDP, but it is a much higher share of GDP within developing countries (C8 Table 8.1). That year, for example, agriculture (including forestry and fishing) represented 24% of total GDP in countries with a per capita GNP less than \$765 (the low-income developing countries, as defined by the World Bank) (C8.5.5.2). The agricultural labor force contained 1.3 billion people globally—approximately a fourth (22%) of the world's population and half (46%) of the total labor force—and some 2.5 billion people, about 40% of the world, lived in agriculturally based households (C8.5.5). Significant differences exist between developing and industrial countries in these patterns. For example, in the United States only 2.4% of the labor force works in agriculture.

Other ecosystem services (or commodities based on ecosystem services) that make significant contributions to national economic activity include timber (around \$400 billion), marine fisheries (around \$80 billion in 2000), marine aquaculture (\$57 billion in 2000), recreational hunting and fishing (\$50 billion, and \$24–37 billion annually in the United States alone), as well as edible forest products, botanical medicines, and medicinal plants (C9.ES, C18.1, C20.ES). And many other industrial products and commodities rely on ecosystem services such as water as inputs.

**The degradation of ecosystem services represents a loss of a capital asset (C5.4.1).** (See Figure 3.1.) Both renewable resources such as ecosystem services and nonrenewable resources such as mineral deposits, soil nutrients, and fossil fuels are capital assets. Yet traditional national accounts do not include measures of resource depletion or of the degradation of renewable resources. As a result, a country could cut its forests and deplete its fisheries, and this would show only as a positive gain to GDP despite the loss of the capital asset. Moreover, many ecosystem services are available

1 freely to those who use them (fresh water in aquifers, for instance, or the use of the  
2 atmosphere as a sink for pollutants), and so again their degradation is not reflected in  
3 standard economic measures.

4 When estimates of the economic losses associated with the depletion of natural assets are  
5 factored into measurements of the total wealth of nations, they significantly change the  
6 balance sheet of those countries with economies especially dependent on natural  
7 resources. For example, countries such as Ecuador, Ethiopia, Kazakhstan, Republic of  
8 Congo, Trinidad and Tobago, Uzbekistan, and Venezuela that had positive growth in net  
9 savings (reflecting a growth in the net wealth of the country) in 2001 actually experienced  
10 a loss in net savings when depletion of natural resources (energy and forests) and  
11 estimated damages from carbon emissions (associated with contributions to climate  
12 change) were factored into the accounts.

13 **The degradation of ecosystem services often causes significant harm to human well-**  
14 **being** (C5 Box 5.1). The information available to assess the consequences of changes in  
15 ecosystem services for human well-being is relatively limited. Many ecosystem services  
16 have not been monitored and it is also difficult to estimate the relative influence of  
17 changes in ecosystem services in relation to other social, cultural, and economic factors  
18 that also affect human well-being. Nevertheless, the following evidence illustrates that the  
19 harmful effects of the degradation of ecosystem services on livelihoods, health, and local  
20 and national economies are substantial.

- 21 ▪ *Most resource management decisions are most strongly influenced by ecosystem*  
22 *services entering markets; as a result, the nonmarketed benefits are often lost or*  
23 *degraded.* Many ecosystem services, such as the purification of water, regulation of  
24 floods, or provision of aesthetic benefits, do not pass through markets. The benefits  
25 they provide to society, therefore, are largely unrecorded: only a portion of the total  
26 benefits provided by an ecosystem make their way into statistics, and many of these  
27 are misattributed (the water regulation benefits of wetlands, for example, do not  
28 appear as benefits of wetlands but as higher profits in water-using sectors). Moreover,  
29 for ecosystem services that do not pass through markets there is often insufficient  
30 incentive for individuals to invest in maintenance (although in some cases common  
31 property management systems provide such incentives). Typically, even if individuals  
32 are aware of the services provided by an ecosystem, they are neither compensated for  
33 providing these services nor penalized for reducing them. These nonmarketed benefits  
34 are often high and sometimes more valuable than the marketed benefits. For example:
  - 35 ○ *Total economic value of forests.* One of the most comprehensive studies to date,  
36 which examined the marketed and nonmarketed economic values associated with  
37 forests in eight Mediterranean countries, found that timber and fuelwood generally  
38 accounted for less than a third of total economic value in each country. (See  
39 Figure 3.2.)
  - 40 ○ *Recreational benefits of protected areas:* The annual recreational value of the  
41 coral reefs of each of six Marine Management Areas in the Hawaiian Islands in  
42 2003 ranged from \$300,000 to \$35 million.
  - 43 ○ *Water quality:* The net present value in 1998 of protecting water quality in the  
44 224-mile Catawba River in the United States for five years was estimated to be  
45 \$346 million.

- 1      ○ *Water purification service of wetlands:* About half of the total economic value of  
2 the Danube River Floodplain in 1992 could be accounted for in its role as a  
3 nutrient sink.
- 4      ○ *Native pollinators:* A study in Costa Rica found that forest-based pollinators  
5 increased coffee yields by 20% within 1 kilometer of the forest (as well as  
6 increasing the quality of the coffee). During 2000–03, pollination services from  
7 two forest fragments (of 46 and 111 hectares) thus increased the income of a  
8 1,100-hectare farm by \$60,000 a year, a value commensurate with expected  
9 revenues from competing land uses.
- 10     ○ *Flood control:* Muthurajawela Marsh, a 3,100-hectare coastal peat bog in Sri  
11 Lanka, provides an estimated \$5 million in annual benefits (\$1,750 per hectare)  
12 through its role in local flood control.
- 13
- 14     ▪ *The total economic value associated with managing ecosystems more sustainably is*  
15 *often higher than the value associated with the conversion of the ecosystem through*  
16 *farming, logging, or other intensive uses.* Relatively few studies have compared the  
17 total economic value (including values of both marketed and nonmarketed ecosystem  
18 services) of ecosystems under alternate management regimes, but a number of studies  
19 that do exist have found that the benefit of managing the ecosystem more sustainably  
20 exceeded that of converting the ecosystem (see Figures 3.3 and 3.4), although the  
21 private benefits—that is, the actual monetary benefits captured from the services  
22 entering the market—would favor conversion or unsustainable management. These  
23 studies are consistent with the understanding that market failures associated with  
24 ecosystem services lead to greater conversion of ecosystems than is economically  
25 justified. However, this finding would not hold at all locations. For example, the value  
26 of conversion of an ecosystem in areas of prime agricultural land or in urban regions  
27 often exceeds the total economic value of the intact ecosystem. (Although even in  
28 dense urban areas, the total economic value of maintaining some “green space” can be  
29 greater than development of these sites.)
- 30
- 31     ▪ *The economic and public health costs associated with damage to ecosystem services*  
32 *can be substantial.*
- 33     ○ The early 1990s collapse of the Newfoundland cod fishery due to overfishing (see  
34 Figure 3.5) resulted in the loss of tens of thousands of jobs and has cost at least \$2  
35 billion in income support and retraining.
- 36     ○ The costs of U.K. agriculture in 1996 associated with damage to water (pollution,  
37 eutrophication), air (emissions of greenhouse gases), soil (off-site erosion damage,  
38 carbon dioxide loss), and biodiversity was \$2.6 billion, or 9% of average yearly  
39 gross farm receipts for the 1990s. Similarly, the damage costs of freshwater  
40 eutrophication alone in England and Wales was estimated to be \$105–160 million  
41 per year in the 1990s, with an additional \$77 million per year being spent to  
42 address those damages.
- 43     ○ The burning of 10 million hectares of Indonesia’s forests in 1997/98 cost an  
44 estimated \$9.3 billion in increased health care, lost production, and lost tourism  
45 revenues and affected some 20 million people across the region.
- 46     ○ The total damages for the Indian Ocean region over 20 years (with a 10% discount  
47 rate) resulting from the long-term impacts of the massive 1998 coral bleaching  
48 episode are estimated to be between \$608 million (if there is only a slight decrease  
49 in tourism-generated income and employment results) and \$8 billion (if tourism

1 income and employment and fish productivity drop significantly and reefs cease  
2 to function as a protective barrier).

- 3 ○ The net annual loss of economic value associated with invasive species in the  
4 fynbos vegetation of the Cape Floral region of South Africa in 1997 was estimated  
5 to be \$93.5 million, equivalent to a reduction of the potential economic value  
6 without the invasive species of more than 40%. The invasive species have caused  
7 losses of biodiversity, water, soil, and scenic beauty, although they also provide  
8 some benefits, such as provision of firewood.
  - 9 ○ The incidence of diseases of marine organisms and emergence of new pathogens  
10 is increasing, and some of these, such as the tropical fish disease Ciguatera, harm  
11 human health (C19.3.1). Episodes of harmful (including toxic) algal blooms in  
12 coastal waters are increasing in frequency and intensity, harming other marine  
13 resources such as fisheries and harming human health (R16 Figure 16.3). In a  
14 particularly severe outbreak in Italy in 1989, harmful algal blooms cost the coastal  
15 aquaculture industry \$10 million and the Italian tourism industry \$11.4 million  
16 (C19.3.1).
  - 17 ○ The number of both floods and fires has increased significantly, in part due to  
18 ecosystem changes, in the past 50 years. Examples are the increased susceptibility  
19 of coastal populations to tropical storms when mangrove forests are cleared and  
20 the increase in downstream flooding that followed land use changes in the upper  
21 Yangtze river (C.SDM). Annual economic losses from extreme events increased  
22 tenfold from the 1950s to approximately \$70 billion in 2003, of which natural  
23 catastrophes—floods, fires, storms, drought, and earthquakes—accounted for 84%  
24 of insured losses.
- 25
- 26 ■ *Significant investments are often needed to restore or maintain nonmarketed*  
27 *ecosystem services.*
    - 28 ○ In South Africa, invasive tree species threaten both native species and water flows  
29 by encroaching into natural habitats, with serious impacts for economic growth  
30 and human well-being. In response, the South African government established the  
31 “Working for Water Programme.” Between 1995 and 2001 the program invested  
32 \$131 million (at 2001 exchange rates) in clearing programs to control the invasive  
33 species.
    - 34 ○ The state of Louisiana has put in place a \$14-billion wetland restoration plan to  
35 protect 10,000 square kilometers of marsh, swamp, and barrier islands in part to  
36 reduce storm surges generated by hurricanes.
- 37

38 **Although degradation of ecosystem services could be significantly slowed or**  
39 **reversed if the full economic value of the services were taken into account in**  
40 **decision-making, economic considerations alone would likely lead to lower levels of**  
41 **biodiversity (*medium certainty*) (CWG).** Although most or all biodiversity has some  
42 economic value (the option value of any species is always greater than zero), that does not  
43 mean that the protection of all biodiversity is always economically justified. Other  
44 utilitarian benefits often “compete” with the benefits of maintaining greater diversity. For  
45 example, many of the steps taken to increase the production of ecosystem services  
46 involve the simplification of natural systems. (Agriculture, for instance, typically has  
47 involved the replacement of relatively diverse systems with more simplified production  
48 systems.) And protecting some other ecosystem services may not necessarily require the  
49 conservation of biodiversity. (For example, a forested watershed could provide clean  
50 water whether it was covered in a diverse native forest or in a single-species plantation.)

1 Ultimately, the level of biodiversity that survives on Earth will be determined not just by  
2 utilitarian considerations but to a significant extent by ethical concerns, including  
3 considerations of the intrinsic values of species.

4 **Even wealthy populations cannot be fully insulated from the degradation of**  
5 **ecosystem services (CWG).** The degradation of ecosystem services influences human  
6 well-being in industrial regions and among wealthy populations in developing countries.

- 7 ○ The physical, economic, or social impacts of ecosystem service degradation may  
8 cross boundaries. (See Figure 3.6.) Land degradation or fires in poor countries,  
9 for example, has contributed to air quality degradation (dust and smoke) in  
10 wealthy ones. Degradation of ecosystem services also exacerbates poverty in  
11 developing countries, which can affect neighboring wealthy countries by slowing  
12 regional economic growth and contributing to the outbreak of conflicts or  
13 migrations of refugees.
- 14 ○ Many sectors of industrial countries still depend directly on ecosystem services.  
15 The collapse of fisheries, for example, has harmed many communities in  
16 industrial countries.
- 17 ○ Wealthy populations are insulated from the harmful effects of some aspects of  
18 ecosystem degradation. but not all. For example, substitutes are typically not  
19 available when cultural services are lost.

20  
21 **While traditional natural resource sectors such as agriculture, forestry, and fisheries**  
22 **are still important in industrial-country economies, the relative economic and**  
23 **political significance of other sectors has grown as a result of the ongoing transition**  
24 **from agricultural to industrial and service economies (S7).** Over the past two  
25 centuries, the economic structure of the world's largest economies has shifted  
26 significantly from agricultural production to industry and, in particular, to service  
27 industries. (See Figure 3.7.) These changes increase the relative significance of the  
28 industrial and service sectors (using conventional economic measures that do not factor in  
29 nonmarketed costs and benefits) in comparison to agriculture, forestry, and fisheries,  
30 although natural resource-based sectors often still dominate in developing countries. In  
31 2000, agriculture accounted for 5% of world GDP, industry 31%, and service industries  
32 64%. At the same time, the importance of other nonmarketed ecosystem services has  
33 grown, although many of the benefits provided by these services are not captured in  
34 national economic statistics. The economic value of water from forested ecosystems near  
35 urban populations, for example, now sometimes exceeds the value of timber in those  
36 ecosystems. Economic and employment contributions from ecotourism, recreational  
37 hunting, and fishing have all grown.

38 **Increased trade has often helped meet growing demand for ecosystem services such**  
39 **as grains, fish, and timber in regions where their supply is limited. While this lessens**  
40 **pressures on ecosystem services within the importing region, it increases pressures**  
41 **in the exporting region.** Fish products are heavily traded, and approximately 50% of  
42 exports are from developing countries. Exports from these nations and the Southern  
43 Hemisphere presently offset much of the shortfall of supply in European, North  
44 American, and East Asian markets (C18.ES). Trade has increased the quantity and quality  
45 of fish supplied to wealthy countries, in particular the United States, those in Europe, and  
46 Japan, despite reductions in marine fish catch (C18.5.1).

1 The value of international trade in forest products has increased much faster than  
2 increases in harvests. (Roundwood harvests grew by 60% between 1961 and 2000, while  
3 the value of international timber trade increased twenty-five-fold (C9.ES).) The United  
4 States, Germany, Japan, United Kingdom, and Italy were the destination of more than  
5 half of the imports in 2000, while Canada, United States, Sweden, Finland, and Germany  
6 account for more than half of the exports.

7 Trade in commodities such as grain, fish, and timber is accompanied by a “virtual trade”  
8 in other ecosystem services that are required to support the production of these  
9 commodities. Globally, the international virtual water trade in crops has been estimated  
10 between 500 and 900 cubic kilometers per year, and 130–150 cubic kilometers per year is  
11 traded in livestock and livestock products. For comparison, current rates of water  
12 consumption for irrigation total 1,200 cubic kilometers per year (C7.3.2).

13 **Changes in ecosystem services affect people living in urban ecosystems both directly**  
14 **and indirectly. Likewise, urban populations have strong impacts on ecosystem**  
15 **services both in the local vicinity and at considerable distances from urban centers**  
16 (C27). Almost half of the world’s population now lives in urban areas, and this proportion  
17 is growing. Urban development often threatens the availability of water, air and water  
18 quality, waste processing, and many other qualities of the ambient environment that  
19 contribute to human well-being, and this degradation is particularly threatening to  
20 vulnerable groups such as poor people. A wide range of ecosystem services are still  
21 important to livelihoods. For example, agriculture practiced within urban boundaries  
22 contributes to food security in urban sub-Saharan Africa. Urban populations affect distant  
23 ecosystems through trade and consumption and are affected by changes in distant  
24 ecosystems that affect the local availability or price of commodities, air or water quality,  
25 or global climate, or that affect socioeconomic conditions in those countries in ways that  
26 influence the economy, demographic, or security situation in distant urban areas.

27 **Spiritual and cultural values of ecosystems are as important as other services for**  
28 **many local communities.** Human cultures, knowledge systems, religions, heritage  
29 values, and social interactions have always been influenced and shaped by the nature of  
30 the ecosystem and ecosystem conditions in which culture is based. People have benefited  
31 in many ways from cultural ecosystem services, including aesthetic enjoyment,  
32 recreation, artistic and spiritual fulfilment, and intellectual development (C17ES). Several  
33 of the MA sub-global assessments highlighted the importance of these cultural services  
34 and spiritual benefits to local communities (SG.SDM). For example, local villages in  
35 India preserve selected sacred groves of forest for spiritual reasons, and urban parks  
36 provide important cultural and recreational services in cities around the world.

37 *Ecosystem Services, Millennium Development Goals, and Poverty Reduction*

38 **The degradation of ecosystem services poses a significant barrier to the achievement**  
39 **of the Millennium Development Goals and to the MDG targets for 2015.** (See Box  
40 3.2.) The regions facing the greatest challenges in achieving the MDGs overlap with the  
41 regions facing the greatest problems related to the sustainable supply of ecosystem  
42 services. Sub-Saharan Africa, Central Asia, and parts of South and Southeast Asia as well  
43 as some regions in Latin America are currently not moving toward meeting the MDGs  
44 (R19.ES). Sub-Saharan Africa has experienced increases in maternal deaths and income  
45 poverty (those living on less than \$1 a day), and the number of people living in poverty  
46 there is forecast to rise from 315 million in 1999 to 404 million by 2015 (R19.1).

1  
2 These regions all face problems of unsustainable use of ecosystem services or declining  
3 per capita supply of services. Per capita food production has been declining in southern  
4 Africa, and relatively little gain is projected in the MA scenarios. Many of these regions  
5 include large areas of drylands, in which a combination of growing populations and land  
6 degradation are increasing the vulnerability of people to both economic and  
7 environmental change. In the past 20 years, these same regions have experienced some of  
8 the highest rates of forest and land degradation in the world.

9  
10 **Despite the progress achieved in increasing the production and use of some**  
11 **ecosystem services, levels of poverty remain high, inequities are growing, and many**  
12 **people still do not have a sufficient supply of or access to ecosystem services (C5).**

- 13 ○ In 2001, some 1.1 billion people survived on less than \$1 per day of income, most  
14 of them (roughly 70%) in rural areas where they are highly dependent on  
15 agriculture, grazing, and hunting for subsistence (R19.2.1).
- 16 ○ Inequality in income and other measures of human well-being has increased over  
17 the past decade (C5.ES). A child born in sub-Saharan Africa is 20 times more  
18 likely to die before age five than a child born in an industrial country, and this  
19 ratio is higher than it was a decade ago. During the 1980s, only four countries  
20 experienced declines in their rankings in the Human Development Index (an  
21 aggregate measure of economic well-being, health, and education); during the  
22 1990s, 21 countries showed declines, and 14 of them were in sub-Saharan Africa.
- 23 ○ Despite the growth in per capita food production in the past four decades, an  
24 estimated 856 million people were undernourished in 2000–03, up 32 million  
25 from 1995–97. Of these, nearly 95% live in developing countries (C8.ES). South  
26 Asia and sub-Saharan Africa, the regions with the largest numbers of  
27 undernourished people, are also the regions where growth in per capita food  
28 production has been the slowest. Most notably, per capita food production has  
29 declined in sub-Saharan Africa (C28.5.1).
- 30 ○ Some 1.1 billion people still lack access to improved water supply and more than  
31 2.6 billion have no access to improved sanitation. Water scarcity affects roughly  
32 1–2 billion people worldwide. Since 1960, the ratio of water use to accessible  
33 supply has grown by 20% per decade (C7.ES, C7.2.3).

34 **The degradation of ecosystem services is harming many of the world’s poorest**  
35 **people and is sometimes the principal factor causing poverty.** This is not to say that  
36 ecosystem changes such as increased food production have not also helped to lift  
37 hundreds of millions of people out of poverty. But these changes have harmed many other  
38 communities, and their plight has been largely overlooked. Examples of these impacts  
39 include:

- 40 ○ Half of the urban population in Africa, Asia, Latin America, and the Caribbean  
41 suffers from one or more diseases associated with inadequate water and sanitation  
42 (C.SDM). Approximately 1.8 million people die annually as a result of inadequate  
43 water, sanitation, and hygiene (C7.ES).
- 44 ○ The declining state of capture fisheries is reducing a cheap source of protein in  
45 developing countries. Per capita fish consumption in developing countries,  
46 excluding China, declined between 1985 and 1997 (C18.ES).

47  
48 **The pattern of “winners” and “losers” associated with ecosystem changes, and in**  
49 **particular the impact of ecosystem changes on poor people, women, and indigenous**

1 **peoples, has not been adequately taken into account in management decisions (R17).**  
2 Changes in ecosystems typically yield benefits for some people and exact costs on others,  
3 who may either lose access to resources or livelihoods or be affected by externalities  
4 associated with the change. For several reasons, groups such as the poor, women, and  
5 indigenous communities have tended to be harmed by these changes.

- 6 ○ Many changes have been associated with the privatization of what were formerly  
7 common pool resources, and the individuals who are dependent on those resources  
8 have thus lost rights to them. This has been particularly the case for indigenous  
9 peoples, forest-dependent communities, and other groups relatively marginalized  
10 from political and economic sources of power.
- 11 ○ Some of the people and places affected by changes in ecosystems and ecosystem  
12 services are highly vulnerable and poorly equipped to cope with the major  
13 ecosystem changes that may occur (C6.ES). Highly vulnerable groups include  
14 those whose needs for ecosystem services already exceed the supply, such as  
15 people lacking adequate clean water supplies and people living in areas with  
16 declining per capita agricultural production. Vulnerability has also been increased  
17 by the growth of populations in ecosystems at risk of disasters such as floods or  
18 drought, often due to inappropriate policies that have encouraged this growth.  
19 Populations are growing in low-lying coastal areas and dryland ecosystems. In  
20 part due to the growth in these vulnerable populations, the number of natural  
21 disasters (floods, droughts, earthquakes, and so on) requiring international  
22 assistance has quadrupled over the past four decades. Finally, vulnerability has  
23 been increased when the resilience in either the social or ecological system has  
24 been diminished, as for example through the loss of drought-resistant crop  
25 varieties.
- 26 ○ Significant differences between the roles and rights of men and women in  
27 developing countries lead to women's increased vulnerability to changes in  
28 ecosystem services. Rural women in developing countries are the main producers  
29 of staple crops like rice, wheat, and maize (R6 Box 6.1). Because the gendered  
30 division of labor within many societies places responsibility for routine care of the  
31 household with women, even when women also play important roles in  
32 agriculture, the degradation of ecosystem services such as water quality or  
33 quantity, fuelwood, agricultural or rangeland productivity often results in  
34 increased labor demands on women. This can affect the larger household by  
35 diverting time from food preparation, child care, education of children, and other  
36 beneficial activities (C6.3.3). Yet gender bias persists in agricultural policies in  
37 many countries, and rural women involved in agriculture tend to be the last to  
38 benefit from—or in some cases are negatively affected by—development policies  
39 and new technologies.
- 40 ○ The reliance of the rural poor on ecosystem services is rarely measured and thus  
41 typically overlooked in national statistics and in poverty assessments, resulting in  
42 inappropriate strategies that do not take into account the role of the environment  
43 in poverty reduction. For example, a recent study that synthesized data from 17  
44 countries found that 22% of household income for rural communities in forested  
45 regions comes from sources typically not included in national statistics, such as  
46 harvesting wild food, fuelwood, fodder, medicinal plants, and timber. These  
47 activities generated a much higher proportion of poorer families' total income—  
48 income that was of particular significance in periods of both predictable and  
49 unpredictable shortfalls in other livelihood sources (R17.?? ).

1 **Poor people have historically lost access to ecosystem services disproportionately as**  
2 **demand for those services has grown.** Coastal habitats are often converted to other uses,  
3 frequently for aquaculture ponds or cage culturing of highly valued species such as  
4 shrimp and salmon. Despite the fact that the area is still used for food production, local  
5 residents are often displaced, and the food produced is usually not for local consumption  
6 but for export (C18.5.1). Many areas where overfishing is a concern are also low-income,  
7 food-deficit countries. For example, significant quantities of fish are caught by large  
8 distant water fleets in the exclusive economic zones of Mauritania, Senegal, Gambia,  
9 Guinea Bissau, and Sierra Leone. Much of the catch is exported or shipped directly to  
10 Europe, while compensation for access is often low compared with the value of the  
11 product landed overseas. These countries do not necessarily benefit through increased fish  
12 supplies or higher government revenues when foreign distant water fleets ply their waters  
13 (C18.5.1).

14 **Diminished human well-being tends to increase immediate dependence on ecosystem**  
15 **services, and the resultant additional pressure can damage the capacity of those**  
16 **ecosystems to deliver services (SG2ES).** As human well-being declines, the options  
17 available to people that allow them to regulate their use of natural resources at sustainable  
18 levels decline as well. This in turn increases pressure on ecosystem services and can  
19 create a downward spiral of increasing poverty and further degradation of ecosystem  
20 services.

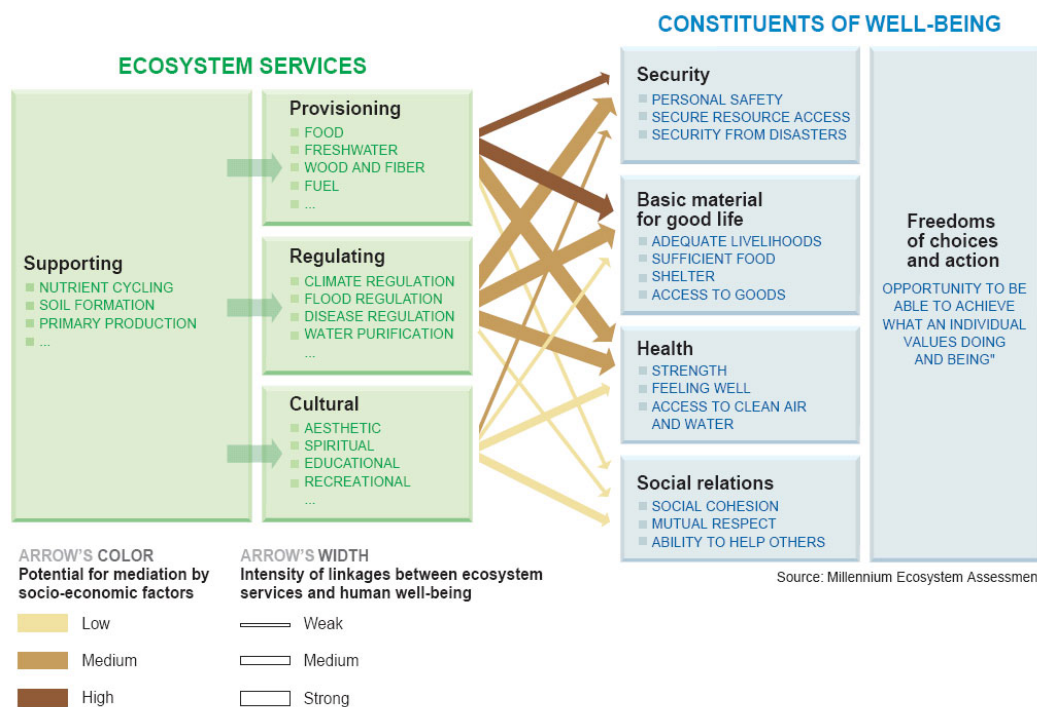

21 **Dryland ecosystems tend to have the lowest levels of human well-being (C5.3.3).**  
22 Drylands have the lowest per capita GDP and the highest infant mortality rates of all of  
23 the MA systems. Nearly 500 million people live in rural areas in dry and semiarid lands,  
24 mostly in Asia and Africa but also in regions of Mexico and northern Brazil (C5 Box 5.2).  
25 The small amount of precipitation and its high variability limit the productive potential of  
26 drylands for settled farming and nomadic pastoralism, and many ways of expanding  
27 production (such as reducing fallow periods, overgrazing pasture areas, and cutting trees  
28 for fuelwood) result in environmental degradation. The combination of high variability in  
29 environmental conditions and relatively high levels of poverty leads to situations where  
30 human populations can be extremely sensitive to changes in the ecosystem (although the  
31 presence of these conditions has led to the development of very resilient land  
32 management strategies). Once rainfall in the Sahel reverted to normal low levels after  
33 1970, following favorable rainfall from the 1950s to the mid-1960s that had attracted  
34 people to the region, an estimated 250,000 people died, along with nearly all their cattle,  
35 sheep, and goats (C5 Box 5.1).

36 **Although population growth has historically been higher in high-productivity**  
37 **ecosystems or urban areas, during the 1990s it was highest in less productive**  
38 **ecosystems (C5.ES, C5.3.4).** In that decade dryland systems (encompassing both rural  
39 and urban regions of drylands) experienced the highest, and mountain systems the second  
40 highest, population growth rate of any of the systems examined in the MA. (See Figure  
41 3.8.) One factor that has helped reduce relative population growth in marginal lands has  
42 been migration of some people out of marginal lands to cities or to agriculturally  
43 productive regions; today the opportunities for such migration are limited due to a  
44 combination of factors, including poor economic growth in some cities, tighter  
45 immigration restrictions in wealthy countries, and limited availability of land in more  
46 productive regions.

### Box 3.1. Linkages between Ecosystem Services and Human Well-being

Human well-being has five main components: the basic material needs for a good life, health, good social relations, security, and freedom of choice and action. (See Box Figure A.) This last component is influenced by other constituents of well-being (as well as by other factors including, notably, education) and is also a precondition for achieving other components of well-being, particularly with respect to equity and fairness. Human well-being is a continuum—from extreme deprivation, or poverty, to a high attainment or experience of well-being. Ecosystems underpin human well-being through supporting, provisioning, regulating, and cultural services. Well-being also depends on the supply and quality of human services, technology, and institutions.

**Figure A. Linkages between Ecosystem Services and Human Well-being.** This figure depicts the strength of linkages between categories of ecosystem services and components of human well-being that are commonly encountered, and includes indications of the extent to which it is possible for socioeconomic factors to mediate the linkage. (For example, if it is possible to purchase a substitute for a degraded ecosystem service, then there is a high potential for mediation.) The strength of the linkages and the potential for mediation differ in different ecosystems and regions. In addition to the influence of ecosystem services on human well-being depicted here, other factors—including other environmental factors as well as economic, social, technological, and cultural factors—influence human well-being, and ecosystems are in turn affected by changes in human well-being.

#### Basic Materials for a Good Life

This refers to the ability to have a secure and adequate livelihood, including income and assets, enough food and water at all times, shelter, ability to have energy to keep warm and cool, and access to goods. Changes in provisioning services such as food, water, and fuelwood have very strong impacts on the adequacy of material for a good life. Access to these materials is heavily mediated by socioeconomic circumstances. For the wealthy, local changes in ecosystems may not cause a significant change in their access to necessary material goods, which can be purchased

1 from other locations, sometimes at artificially low prices if governments provide subsidies (for  
2 example, water delivery systems). Changes in regulating services influencing water supply,  
3 pollination and food production, and climate have very strong impacts on this element of human  
4 well-being. These, too, can be mediated by socioeconomic circumstances, but to a smaller extent.  
5 Changes in cultural services have relatively weak linkages to material elements of well-being.  
6 Changes in supporting services have a strong influence by virtue of their influence on  
7 provisioning and regulating services. The following are some examples of material components of  
8 well-being affected by ecosystem change.  
9

- 10 ▪ *Income and Employment:* Increased production of crops, fisheries, and forest products has  
11 been associated with significant growth in local and national economies. Changes in the use  
12 and management of these services can either increase employment (as, for example, when  
13 agriculture spreads to new regions) or decrease it through gains in productivity of labor. In  
14 regions where productivity has declined due to land degradation or overharvesting of  
15 fisheries, the impacts on local economies and employment can be devastating to the poor or to  
16 those who rely on these services for income.  
17
- 18 ▪ *Food:* The growth in food production and farm productivity has more than kept pace with  
19 global population growth, resulting in significant downward pressure on the price of  
20 foodstuffs. Following significant spikes in the 1970s caused primarily by oil crises, there have  
21 been persistent and profound reductions in the price of foodstuffs globally (C8.1). Over the  
22 last 40 years, food prices have dropped by around 40% in real terms due to increases in  
23 productivity (C26.2.3). It is *well established* that past increases in food production, at  
24 progressively lower unit cost, have improved the health and well-being of billions,  
25 particularly the most needy, who spend the largest share of their incomes on food (C8.1).  
26 Increased production of food and lower prices for food have not been entirely positive.  
27 Among industrial countries, and increasingly among developing ones, diet-related risks,  
28 mainly associated with overnutrition, in combination with physical inactivity now account for  
29 one third of the burden of disease (R16.1.2). At present, over 1 billion adults are overweight,  
30 with at least 300 million considered clinically obese, up from 200 million in 1995 (C8.5.1).  
31
- 32 ▪ *Water Availability:* The modification of rivers and lakes through the construction of dams and  
33 diversions has increased the water available for human use in many regions of the world.  
34 However, the declining per capita availability of water is having negative impacts on human  
35 well-being. Water scarcity is a globally significant and accelerating condition for roughly 1–2  
36 billion people worldwide, leading to problems with food production, human health, and  
37 economic development. Rates of increase in a key water scarcity measure (water use relative  
38 to accessible supply) from 1960 to the present averaged nearly 20% per decade globally, with  
39 values of 15% to more than 30% per decade for individual continents (C7.ES).  
40

## 41 **Health**

42 By health, we refer to the ability of an individual to feel well and be strong, or in other words to  
43 be adequately nourished and free from disease, to have access to adequate and clean drinking  
44 water and clean air, and to have the ability to have energy to keep warm and cool. Human health  
45 is both a product and a determinant of well-being. Changes in provisioning services such as food,  
46 water, medicinal plants, and access to new medicines and changes in regulating services that  
47 influence air quality, water quality, disease regulation, and waste treatment also have very strong  
48 impacts on health. Changes in cultural services can have strong influences on health, since they  
49 affect spiritual, inspirational, aesthetic, and recreational opportunities, and these in turn affect  
50 both physical and emotional states. Changes in supporting services have a strong influence on all  
51 of the other categories of services. These benefits are moderately mediated by socioeconomic  
52 circumstances. The wealthy can purchase substitutes for some health benefits of ecosystems (such  
53 as medicinal plants or water quality), but they are more susceptible to changes affecting air

1 quality. The following are some examples of health components of well-being affected by  
2 ecosystem change.

- 3
- 4 ▪ *Vector-borne Disease:* Actions to reduce vector-borne diseases have resulted in major health  
5 gains and helped to relieve important constraints on development in poor regions. Vector-  
6 borne diseases cause approximately 1.4 million deaths a year, mainly due to malaria in Africa.  
7 These infections are both an effect and a cause of poverty (R12-ES). Prevalence of a number  
8 of infectious diseases appears to be growing, and environmental changes such as deforestation,  
9 dam construction, road building, agricultural conversion, and urbanization are contributing  
10 factors in many cases (C14.2).
- 11
- 12 ▪ *Medicines:* The use of natural products in the pharmaceutical industry has tended to fluctuate  
13 widely, with a general decline in pharmaceutical bioprospecting by major companies.  
14 Historically, most drugs were obtained from natural products. Even near the end of the  
15 twentieth century, approximately 50% of prescription medicines were originally discovered in  
16 plants (C10.2). Natural products still are actively used in drug exploration. Medicinal plants  
17 continue to play an important role in health care systems in many parts of the world. One MA  
18 sub-global assessment in the Mekong wetlands identified more than 280 medically important  
19 plant species, of which 150 are still in regular use (C10.2.2). Medicinal plants have generally  
20 declined in availability due to overharvesting and loss of habitats (C10.5.4).
- 21
- 22 ▪ *Nutrition:* In 2000, about a quarter of the burden of disease among the poorest countries was  
23 attributable to childhood and maternal undernutrition. Worldwide, undernutrition accounted  
24 for nearly 10% of the global burden of disease (R16.1.2).
- 25
- 26 ▪ *Water and Sanitation:* The burden of disease from inadequate water, sanitation, and hygiene  
27 totals 1.8 million deaths and results in the loss of at least 70 million healthy life years  
28 annually. Along with sanitation, water availability and quality are well recognized as  
29 important risk factors for infectious diarrhea and other major diseases. (See Box Table.) Some  
30 1.1 billion people lack access to clean drinking water, and more than 2.6 billion lack access to  
31 sanitation (C7.ES). (See Box Figures B and C.) Globally, the economic cost of pollution of  
32 coastal waters is estimated to be \$16 billion annually, mainly due to human health impacts  
33 (C19.3.1).

34 <insert Box Table here>

35  
36 <Insert Box Figures B and C here>

37  
38  
39 **[[I switched order of the next two, to match list in opening para]]**

#### 40 41 **Good Social Relations**

42 Good social relations refer to the presence of social cohesion, mutual respect, and the ability to  
43 help others and provide for children. Changes in provisioning and regulating ecosystem services  
44 can affect social relations, principally through their more direct impacts on material well-being,  
45 health, and security. Changes in cultural services can have a strong influence on social relations,  
46 particularly in cultures that have retained strong connections to local environments. Changes in  
47 provisioning and regulating services can be mediated by socioeconomic factors, but those in  
48 cultural services cannot. Even a wealthy country like Sweden or the United Kingdom cannot  
49 readily purchase a substitute to a cultural landscape that is valued by the people in the community.

50  
51 Changes in ecosystems have tended to increase the accessibility that people have to ecosystems  
52 for recreation and ecotourism. There are clear examples of declining ecosystem services  
53 disrupting social relations or resulting in conflicts. Indigenous societies whose cultural identities

1 are tied closely to particular habitats or wildlife suffer if habitats are destroyed or wildlife  
2 populations decline. Such impacts have been observed in coastal fishing communities, Arctic  
3 populations, traditional forest societies, and pastoral nomadic societies (C5.4.4).

## 5 **Security**

6 By security, we refer to safety of person and possessions, secure access to necessary resources,  
7 and security from natural and human-made disasters. Changes in regulating services such as  
8 disease regulation, climate regulation, and flood regulation have very strong influences on  
9 security. Changes in provisioning services such as food and water have strong impacts on security,  
10 since degradation of these can lead to loss of access to these essential resources. Changes in  
11 cultural services can influence security since they can contribute to the breakdown or  
12 strengthening of social networks within society. Changes in supporting services have a strong  
13 influence by virtue of their influence on all the other categories of services. These benefits are  
14 moderately mediated by socioeconomic circumstances. The wealthy have access to some safety  
15 nets that can minimize the impacts of some ecosystem changes (such as flood or drought  
16 insurance). Nevertheless, the wealthy cannot entirely escape exposure to some of these changes in  
17 areas where they live.

18  
19 One example of an aspect of security affected by ecosystem change involves influences on the  
20 severity and magnitude of floods and major fires. The incidence of these has increased  
21 significantly over the past 50 years. Changes in ecosystems and in the management of ecosystems  
22 have contributed to these trends. The canalization of rivers, for example, tends to decrease the  
23 incidence and impact of small flood events and increase the incidence and severity of large ones.  
24 On average, 140 million people are affected by floods each year—more than all other natural or  
25 technological disasters put together. Between 1990 and 1999, more than 100,000 people were  
26 killed in floods, which caused a total of \$243 billion in damages (C7.4.4).

## 28 **Freedom of Choice and Action**

29 Freedom and choice refer to the ability of individuals to control what happens to them and to be  
30 able to achieve what they value doing or being. Freedom and choice cannot exist without the  
31 presence of the other elements of well-being, so there is an indirect influence of changes in all  
32 categories of ecosystem services on the attainment of this constituent of well-being. The influence  
33 of ecosystem change on freedom and choice is heavily mediated by socioeconomic circumstances.  
34 The wealthy and people living in countries with efficient governments and strong civil society can  
35 maintain freedom and choice even in the face of significant ecosystem change, while this would  
36 be impossible for the poor if, for example, the ecosystem change resulted in a loss of livelihood.

37  
38 In the aggregate, the state of our knowledge about the impact that changing ecosystem conditions  
39 have on freedom and choice is severely limited. Declining provision of fuelwood and drinking  
40 water have been shown to increase the amount of time needed to collect such basic necessities,  
41 which in turn reduces the amount of time available for education, employment, and care of family  
42 members. Such impacts are typically thought to be disproportionately experienced by women  
43 (although the empirical foundation for this view is relatively limited) (C5.4.2).

### 45 **Tables and Figures for Box 3.1:**

46 **Box Table. Selected Water-related Diseases.** Approximate yearly number of cases, mortality,  
47 and disability-adjusted life years. The DALY is a summary measure of population health,  
48 calculated on a population scale as the sum of years lost due to premature mortality and the  
49 healthy years lost due to disability for incident cases of the ill-health condition (C7 Table 7.10).

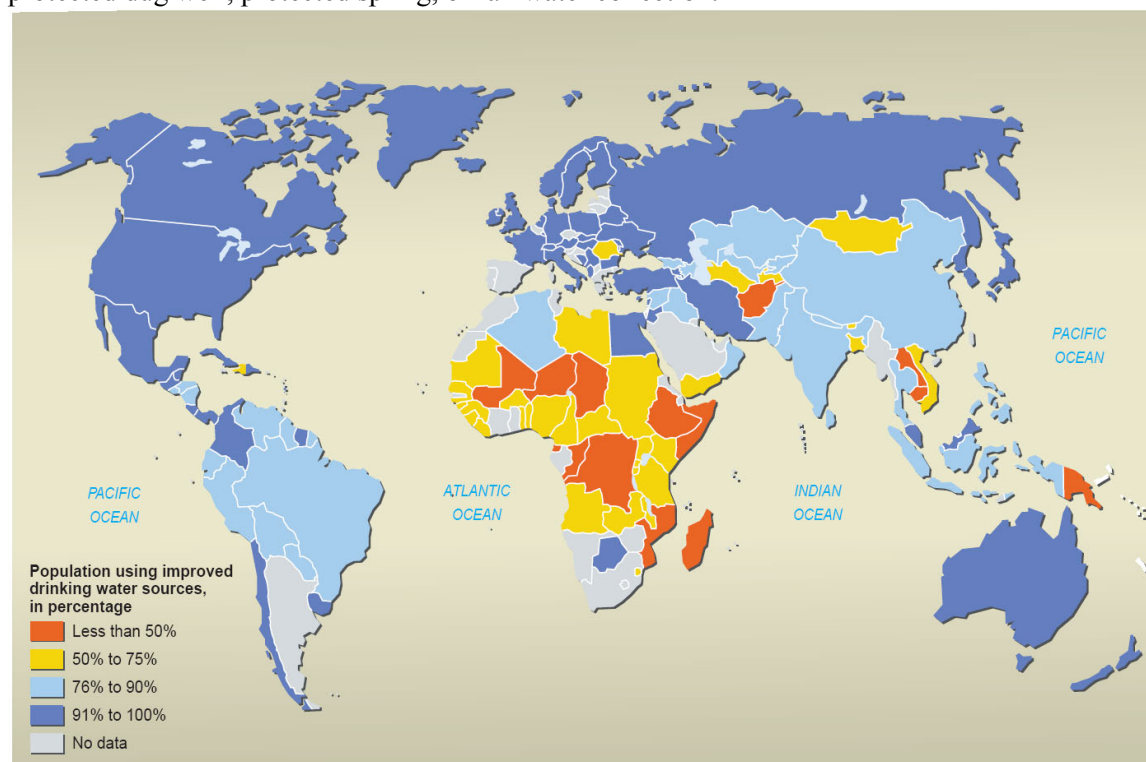

Disease	Number Of Cases	Disability Adjusted Life	Estimated Mortality	Relationship To Freshwater Services
---------	-----------------	--------------------------	---------------------	-------------------------------------

		Years (1000 Dalys)	(1000s)	
Diarrhea	4 billion	62,000	1,800	Water contaminated by human faeces
Malaria	300-500 million	46,500	1,300	Transmitted by Anopheles mosquitoes
Schistosomiasis	200 million	1,700	15	Transmitted by aquatic mollusks
Dengue and dengue hemorrhagic fever	50 to 100 million dengue & 500,000 DHF	616	19	Transmitted by Aedes mosquitoes
Onchocerciasis (River Blindness)	18 million	484	0	Transmitted by black fly
Typhoid and paratyphoid fevers	17 million			Contaminated water, food, flooding
Trachoma	150 million with 6 million blind	2,300	0	Lack of basic hygiene
Cholera	140,000 to 184,000 <sup>a</sup>		5 to 28 <sup>a</sup>	Water and food contaminated by human faeces
Dracunculiasis (Guinea Worm Disease)	96,000			Contaminated water

<sup>a</sup> The upper part of the range refers specifically to 2001.

### Box 3.2. Ecosystems and the Millennium Development Goals

The eight Millennium Development Goals were endorsed by governments at the United Nations in September 2000. The MDGs aim to improve human well-being by reducing poverty, hunger, and child and maternal mortality; ensuring education for all; controlling and managing diseases; tackling gender disparity; ensuring sustainable development; and pursuing global partnerships. For each MDG, governments have agreed to between 1 and 8 targets (a total of 15 targets) that are to be achieved by 2015. Slowing or reversing the degradation of ecosystem services will contribute significantly to the achievement of many of the MDGs.

- *Poverty Eradication:* Ecosystem services are a dominant influence on livelihoods of most poor people. Most of the world's poorest people live in rural areas and are thus highly dependent, directly or indirectly, on the ecosystem service of food production, including agriculture, livestock, and hunting (R19.2.1). Mismanagement of ecosystems threatens the livelihood of poor people and may threaten their survival (C5.ES). Poor people are highly vulnerable to changes in watershed services that affect the quality or availability of water, loss of ecosystems such as wetlands, mangroves, or coral reefs that affect the likelihood of flood or storm damage, or changes in climate regulating services that might alter regional climate. Ecosystem degradation is often one of the factors trapping people in cycles of poverty.
- *Hunger Eradication* (R19.2.2). Although economic and social factors are often the primary determinants of hunger, food production remains an important factor, particularly among the rural poor. Food production is an ecosystem service in its own right, and it also depends on watershed services, pollination, pest regulation, and soil formation. Food production needs to increase to meet the needs of the growing human population, and at the same time the efficiency of food production (the amount produced per unit of land, water, and other inputs) needs to increase in order to reduce harm to other key ecosystem services.
- *Combating Disease* (R19.2.7). Human health is strongly influenced by ecosystem services related to food production, water quality, water quantity, and natural hazard regulation, and the role of ecosystem management is central to addressing some of the most pressing global diseases such as malaria. Changes in ecosystems influence the abundance of human pathogens such as malaria and cholera as well as the risk of emergence of new diseases. Malaria is responsible for 11% of the disease burden in Africa, and it is estimated that Africa's GDP could have been \$100 billion larger (roughly a 25% increase) in 2000 if malaria had been eliminated 35 years ago (R16.1).
- *Environmental Sustainability.* Achievement of this goal will require, at a minimum, an end to the current unsustainable uses of ecosystem services such as fisheries and fresh water and an end to the degradation of other services such as water purification, natural hazard regulation, disease regulation, climate regulation, and cultural amenities.

4 **Adjusted for Investments in Human**  
6 **Capital, Natural Resource Depletion, and**  
8 **Damage Caused by Pollution Compared**  
10 **with Standard Net National Savings**  
12 **Measurements (C5).** Positive values for  
14 national savings reflect a gain in wealth for  
16 a nation. Standard measures do not  
18 incorporate investments in human capital  
20 (in standard national accounting, these  
22 expenditures are treated as consumption),  
24 depletion of a variety of natural resources,  
26 or pollution damages. The World Bank  
28 provides estimates of adjusted net national  
30 savings, taking into account education  
32 expenses (which are added to standard  
34 measures), unsustainable forest harvest,  
36 depletion of nonrenewable resources  
38 (minerals and energy), and damage from  
40 carbon emissions (all of which are  
42 subtracted from the standard measure). The  
44 adjusted measure still overestimates actual  
46 net national savings, since it does not  
48 include potential changes in many  
50 ecosystem services including depletion of  
52 fisheries, atmospheric pollution,  
54 degradation of sources of fresh water, and  
56 loss of noncommercial forests and the  
58 ecosystem services they provide. Here we  
60 show the change in net national savings for  
62 countries in which there was at least a  
64 decline of at least 5% in net national  
66 savings due to the incorporation of resource  
68 depletion or damage from carbon  
70 emissions. The numbers in brackets after  
72 the country name refer to the net decrease  
74 in national savings due to resource  
76 depletion and atmospheric pollution.

1 **Figure 3.5. Collapse of Atlantic Cod Stocks Off the East Coast of Newfoundland in**  
2 **1992.** This collapse forced the closure of the fishery after hundreds of years of  
3 exploitation. Until the late 1950s, the fishery was exploited by migratory seasonal fleets  
4 and resident inshore small-scale fishers. From the late 1950s, offshore bottom trawlers  
5 began exploiting the deeper part of the stock, leading to a large catch increase and a  
6 strong decline in the underlying biomass. The stock collapsed to extremely low levels in  
7 the late 1980s and early 1990s, and a moratorium on commercial fishing was declared in  
8 June 1992. A small commercial inshore fishery was reintroduced in 1998, but catch rates  
9 declined and the fishery was closed indefinitely in 2003.

## 4. What are the most critical factors causing ecosystem changes?

Natural or human-induced factors that directly or indirectly cause a change in an ecosystem are referred to as “drivers.” A *direct driver* unequivocally influences ecosystem processes. An *indirect driver* operates more diffusely, by altering one or more direct drivers.

**Drivers affect ecosystem services and human well-being at different spatial and temporal scales, which makes both their assessment and their management complex** (SG7). Climate change may operate on a global or a large regional spatial scale; political change may operate at the scale of a nation or a municipal district. Sociocultural change typically occurs slowly, on a time scale of decades (although abrupt changes can sometimes occur, as in the case of wars or political regime changes), while economic changes tend to occur more rapidly. As a result of this spatial and temporal dependence of drivers, the forces that appear to be most significant at a particular location and time may not be the most significant over larger (or smaller) regions or time scales.

### *Indirect Drivers*

**In the aggregate and at a global scale, there are five indirect drivers of changes in ecosystems and their services: population change, change in economic activity, sociopolitical factors, cultural factors, and technological change.** Collectively these factors influence the level of production and consumption of ecosystem services and the sustainability of production. Both economic growth and population growth lead to increased consumption of ecosystem services, although the harmful environmental impacts of any particular level of consumption depend on the efficiency of the technologies used in the production of the service. These factors interact in complex ways in different locations to change pressures on ecosystems and uses of ecosystem services. Driving forces are almost always multiple and interactive, so that a one-to-one linkage between particular driving forces and particular changes in ecosystems rarely exists. Even so, changes in any one of these indirect drivers generally result in changes in ecosystems. The causal linkage is almost always highly mediated by other factors, thereby complicating statements of causality or attempts to establish the proportionality of various contributors to changes. There are five major indirect drivers:

- *Demographic Drivers:* Global population doubled in the past 40 years and increased by 2 billion people in the last 25 years, reaching 6 billion in 2000 (S7.2.1). Developing countries have accounted for most recent population growth in the past quarter-century, but there is now an unprecedented diversity of demographic patterns across regions and countries. Some high-income countries such as the United States are still experiencing high rates of population growth, while some developing countries such as China, Thailand, and North and South Korea have very low rates. In the United States, high population growth is due primarily to high levels of immigration. About half the people in the world now live in urban areas (although urban areas cover less than 3% of the terrestrial surface), up from less than 15% at the start of the twentieth century (C27.1). High-income countries typically have populations that are 70–80% urban. Some developing-country regions, such as parts of Asia, are still largely rural, while Latin America, at 75% urban, is indistinguishable from high-income countries in this regard (S7.2.1).

1     ▪ *Economic Drivers:* Global economic activity increased nearly sevenfold between  
2     1950 and 2000 (S7.SDM). With rising per capita income, the demand for many  
3     ecosystem services grows. At the same time, the structure of consumption changes. In  
4     the case of food, for example, as income grows the share of additional income spent  
5     on food declines, the importance of starchy staples (such as rice, wheat, and potatoes)  
6     declines, diets include more fat, meat and fish, and fruits and vegetables, and the  
7     proportionate consumption of industrial goods and services rises (S7.2.2).

8     In the late twentieth century, income was distributed unevenly, both within countries  
9     and around the world. The level of per capita income was highest in North America,  
10    Western Europe, Australasia, and Northeast Asia, but both GDP and per capita  
11    growth rates were highest in South Asia, China, and parts of South America (S7.2.2).  
12    (See Figure 4.1 and 4.2.) Growth in international trade flows has exceeded growth in  
13    global production for many years, and the differential may be growing. In 2001,  
14    international trade in goods was equal to 40% of Gross World Product. (S7.2.2).

15    Inappropriate taxes and subsidies are important indirect drivers of ecosystem change.  
16    Fertilizer taxes or taxes on excess nutrients, for example, provide an incentive to  
17    increase the efficiency of the use of fertilizer applied to crops and thereby reduce  
18    negative externalities. Currently, many subsidies are having the effect of substantially  
19    raising rates of resource consumption and increasing negative externalities. Annual  
20    subsidies to conventional energy, which encourage greater use of fossil fuels and  
21    consequently emissions of greenhouse gases, are estimated to have been \$250–300  
22    billion in the mid-1990s (S7.ES). The 2001–03 average subsidies paid to the  
23    agricultural sectors of OECD countries were over \$324 billion annually (S7.ES),  
24    encouraging greater food production and associated water consumption and nutrient  
25    and pesticide release. At the same time, many developing countries also have  
26    significant agricultural production subsidies.

27    ▪ *Sociopolitical Drivers:* Sociopolitical drivers encompass the forces influencing  
28    decision-making and include the quantity of public participation in decision-making,  
29    the groups participating in public decision-making, the mechanisms of dispute  
30    resolution, the role of the state relative to the private sector, and levels of education  
31    and knowledge (S7.2.3). These factors in turn influence the institutional arrangements  
32    for ecosystem management, as well as property rights over ecosystem services. Over  
33    the past 50 years there have been significant changes in sociopolitical drivers. There is  
34    a declining trend in centralized authoritarian governments and a rise in elected  
35    democracies. The role of women is changing in many countries, average levels of  
36    formal education are increasing, and there has been a rise in civil society (such as  
37    increased involvement of NGOs and grassroots organizations in decision-making  
38    processes). The trend toward democratic institutions has helped give power to local  
39    communities, especially women and resource-poor households (S7.2.3). There has  
40    been an increase in multilateral environmental agreements. The importance of the  
41    state relative to the private sector—as a supplier of goods and services, as a source of  
42    employment, and as a source of innovation—is declining.

43    ▪ *Cultural and Religious Drivers:* To understand culture as a driver of ecosystem  
44    change, it is most useful to think of it as the values, beliefs, and norms that a group of  
45    people share. In this sense, culture conditions individuals' perceptions of the world,  
46    influences what they consider important, and suggests what courses of action are

1 appropriate and inappropriate (S7.2.4). Broad comparisons of whole cultures have not  
2 proved useful because they ignore vast variations in values, beliefs, and norms within  
3 cultures. Nevertheless, cultural differences clearly have important impacts on direct  
4 drivers. Cultural factors, for example, can influence consumption behavior (what and  
5 how much people consume) and values related to environmental stewardship, and  
6 they may be particularly important drivers of environmental change.

- 7 ■ *Science and Technology:* The development and diffusion of scientific knowledge and  
8 technologies that exploit that knowledge has profound implications for ecological  
9 systems and human well-being. The twentieth century saw tremendous advances in  
10 understanding how the world works physically, chemically, biologically, and socially  
11 and in the applications of that knowledge to human endeavors. Science and  
12 technology are estimated to have accounted for more than one third of total GDP  
13 growth in the United States from 1929 to the early 1980s, and for 16–47% of GDP  
14 growth in selected OECD countries in 1960–95 (S7.2.5). The impact of science and  
15 technology on ecosystem services is most evident in the case of food production.  
16 Much of the increase in agricultural output over the past 40 years has come from an  
17 increase in yields per hectare rather than an expansion of area under cultivation. For  
18 instance, wheat yields rose 208%, rice yields rose 109%, and maize yields rose 157%  
19 in the past 40 years in developing countries (S7.2.5). At the same time, technological  
20 advances can also lead to the degradation of ecosystem services. Advances in fishing  
21 technologies, for example, have contributed significantly to the depletion of marine  
22 fish stocks.

23 **Consumption of ecosystem services is slowly being decoupled from economic**  
24 **growth.** Growth in the use of ecosystem services over the past five decades was generally  
25 much less than the growth in GDP. This change reflects structural changes in economies,  
26 but it also results from new technologies and new management practices and policies that  
27 have increased the efficiency with which ecosystem services are used and provided  
28 substitutes for some services. Even with this progress, though, the absolute level of  
29 consumption of ecosystem services continues to grow, which is consistent with the  
30 pattern for the consumption of energy and materials such as metals: in the 200 years for  
31 which reliable data are available, growth of consumption of energy and materials has  
32 outpaced increases in materials and energy efficiency, leading to absolute increases of  
33 materials and energy use (S7.ES).

34 **Global trade magnifies the effect of governance, regulations, and management**  
35 **practices on ecosystems and their services, enhancing good practices but worsening**  
36 **the damage caused by poor practices** (R8, S7). Increased trade can accelerate  
37 degradation of ecosystem services in exporting countries if their policy, regulatory, and  
38 management systems are inadequate. At the same time, international trade enables  
39 comparative advantages to be exploited and accelerates the diffusion of more-efficient  
40 technologies and practices. For example, the increased demand for forest products in  
41 many countries stimulated by growth in forest products trade can lead to more rapid  
42 degradation of forests in countries with poor systems of regulation and management, but  
43 can also stimulate a “virtuous cycle” if the regulatory framework is sufficiently robust to  
44 prevent resource degradation while trade, and profits, increase. While historically most  
45 trade related to ecosystems has involved provisioning services such as food, timber, fiber,  
46 genetic resources, and biochemicals, one regulating service—climate regulation, or more  
47 specifically carbon sequestration—is now also traded internationally.

1 **Urban demographic and economic growth has been increasing pressures on**  
2 **ecosystems globally, but affluent rural and suburban living often places even more**  
3 **pressure on ecosystems (C27-ES).** Dense urban settlement is considered to be less  
4 environmentally burdensome than urban and suburban sprawl. And the movement of  
5 people into urban areas has significantly lessened pressure on some ecosystems and, for  
6 example, has led to the reforestation of some parts of industrial countries that had been  
7 deforested in previous centuries. At the same time, urban centers facilitate human access  
8 to and management of ecosystem services through, for example, economies of scale  
9 related to the construction of piped water systems in areas in areas of high population  
10 density.

### 11 *Direct Drivers*

13 **Most of the direct drivers of degradation in ecosystem services currently remain**  
14 **constant or are growing in intensity in most ecosystems.** (See Figure 4.3.) The most  
15 important direct drivers of change in ecosystem services are habitat change (land use  
16 change and physical modification of rivers or water withdrawal from rivers),  
17 overexploitation, invasive alien species, pollution, and climate change.

19 **For terrestrial ecosystems, the most important direct drivers of change in ecosystem**  
20 **services in the past 50 years, in the aggregate, have been land cover change (in**  
21 **particular, conversion to cropland) and the application of new technologies (which**  
22 **have contributed significantly to the increased supply of services such as food,**  
23 **timber, and fiber) (CWG, S7.2.5, SG8.ES).** In 9 of the 14 biomes examined in the MA,  
24 between one half and one fifth of the area has been transformed, largely to croplands  
25 (C4.ES). Only biomes relatively unsuited to crop plants, such as deserts, boreal forests,  
26 and tundra, have remained largely untransformed by human action. Both land cover  
27 changes and the management practices and technologies used on lands may cause major  
28 changes in ecosystem services. New technologies have resulted in significant increases in  
29 the supply of some ecosystem services, such as through increases in agricultural yield. In  
30 the case of cereals, for example, from the mid-1980s to the late 1990s the global area  
31 under cereals fell by around 0.3% a year, while yields increased by about 1.2% a year  
32 (C26.4.1).

33 **For marine ecosystems and their services, the most important direct driver of**  
34 **change in the past 50 years, in the aggregate, has been fishing (C18).** At the beginning  
35 of the twenty-first century, the biological capability of commercially exploited fish stocks  
36 was probably at a historical low. FAO estimates that about half of the wild marine fish  
37 stocks for which information is available are fully exploited and offer no scope for  
38 increased catches (C8.2.2). As noted in Chapter 1, fishing pressure is so strong in some  
39 marine systems that the biomass of some targeted species, especially larger fishes, and  
40 those caught incidentally has been reduced to one tenth of levels prior to the onset of  
41 industrial fishing (C18.ES). Fishing has had a particularly significant impact in coastal  
42 areas but is now also affecting the open oceans.

43 **For freshwater ecosystems and their services, depending on the region, the most**  
44 **important direct drivers of change in the past 50 years include modification of water**  
45 **regimes, invasive species, and pollution, particularly high levels of nutrient loading.**  
46 It is *speculated* that 50% of inland water ecosystems (excluding large lakes and closed  
47 seas) were converted during the twentieth Century (C20.ES). Massive changes have been

1 made in water regimes: in Asia, 78% of the total reservoir volume was constructed in the  
2 last decade, and in South America almost 60% of all reservoirs have been built since the  
3 1980s (C20.4.2). The introduction of nonnative invasive species is one of the major  
4 causes of species extinction in freshwater systems. While the presence of nutrients such  
5 as phosphorus and nitrogen is necessary for biological systems, high levels of nutrient  
6 loading cause significant eutrophication of water bodies and contribute to high levels of  
7 nitrate in drinking water in some locations. (The nutrient load refers to the total amount of  
8 nitrogen or phosphorus entering the water during a given time.) Non-point pollution  
9 sources such as storm water runoff in urban areas, poor or nonexistent sanitation facilities  
10 in rural areas, and the flushing of livestock manure by rainfall and snowmelt are also  
11 cause of contamination (C20.4.5). Pollution from point sources such as mining has had  
12 devastating local and regional impacts on the biota of inland waters.

13 **Coastal ecosystems are affected by multiple direct drivers.** Fishing pressures in coastal  
14 ecosystems are compounded by a wide array of other drivers, including land-, river-, and  
15 ocean-based pollution, habitat loss, invasive species, and nutrient loading. Upstream  
16 freshwater diversion has meant a 30% decrease worldwide of water and sediment delivery  
17 to estuaries, which are key nursery areas and fishing grounds (C19.ES). Approximately  
18 17% of the world lives within the boundaries of the MA coastal system (up to an  
19 elevation of 50 meters above sea level and no further than 100 kilometers from a coast),  
20 and approximately 40% live in the full area within 50 kilometers of a coast. And the  
21 absolute number is increasing through a combination of in-migration, high reproduction  
22 rates, and tourism (C.SDM). Demand on coastal space for shipping, waste disposal,  
23 military and security uses, recreation, and aquaculture is increasing.

24 The greatest threat to coastal systems is the development-related conversion of coastal  
25 habitats such as forests, wetlands, and coral reefs through coastal urban sprawl, resort and  
26 port development, aquaculture, and industrialization. Dredging, reclamation and  
27 destructive fishing also account for widespread, effectively irreversible destruction. Shore  
28 protection structures and engineering works (beach armoring, causeways, bridges, and so  
29 on), by changing coastal dynamics, have impacts extending beyond their direct footprints.  
30 Nitrogen loading to the coastal zone has increased by about 80% worldwide and has  
31 driven coral reef community shifts (C.SDM).

32 **Over the past four decades, excessive nutrient loading has emerged as one of the**  
33 **most important direct drivers of ecosystem change in terrestrial, freshwater, and**  
34 **marine ecosystems.** (See Table 4.1.) While the introduction of nutrients into ecosystems  
35 can have both beneficial effects (such as increased crop productivity) and adverse effects  
36 (such as eutrophication of inland and coastal waters), the beneficial effects will eventually  
37 reach a plateau as more nutrients are added (that is, additional inputs will not lead to  
38 further increases in crop yield) while the harmful effects will continue to grow. Synthetic  
39 production of nitrogen fertilizer has been an important driver for the remarkable increase  
40 in food production that has occurred during the past 50 years (S7.3.2). World  
41 consumption of nitrogenous fertilizers grew nearly eightfold between 1960 and 2003, from  
42 10.8 million tons to 85.1 million tons. As much as 50% of the nitrogen fertilizer applied  
43 may be lost to the environment, depending on how well the application is managed. Since  
44 excessive nutrient loading is largely the result of applying more nutrients than crops can  
45 use, it harms both farm incomes and the environment. (S7.3.2). Ecological and  
46 environmental effects of excessive flows of nitrogen include eutrophication of freshwater  
47 and coastal marine ecosystems, contribution to acid rain with effects on both freshwater

1 and terrestrial ecosystems, loss of biodiversity in both aquatic and terrestrial ecosystems,  
2 creation of ground-level ozone (which leads to loss of agricultural and forest  
3 productivity), destruction of ozone in the stratosphere (which leads to depletion of the  
4 ozone layer and increased UV-B radiation on Earth), and contribution to global warming.  
5 The resulting health effects include the consequences of ozone pollution on asthma and  
6 respiratory function, increased allergies and asthma due to increased pollen production,  
7 risk of blue-baby syndrome, increased risk of cancer and other chronic diseases from  
8 nitrate in drinking water, and increased risk of a variety of pulmonary and cardiac  
9 diseases from production of fine particles in the atmosphere. (R9.ES)

10 Phosphorus application has increased threefold since 1960, with a steady increase until  
11 1990 followed by a leveling off at a level approximately equal to applications in the  
12 1980s. While phosphorus use has increasingly concentrated on phosphorus-deficient  
13 soils, the growing phosphorus accumulation in soils contributes to high levels of  
14 phosphorus runoff. As with nitrogen loading, the potential consequences include  
15 eutrophication of coastal and freshwater ecosystems, which can lead to degraded habitat  
16 for fish and decreased quality of water for consumption by humans and livestock.

17 Many ecosystem services are reduced when inland waters and coastal ecosystems become  
18 eutrophic. Water from lakes that experience algal blooms is more expensive to purify for  
19 drinking or other industrial uses. Eutrophication can reduce or eliminate fish populations.  
20 Possibly the most striking loss in services is the loss of many of the cultural services  
21 provided by lakes. Foul odors of rotting algae, slime-covered lakes, and toxic chemicals  
22 produced by some blue-green algae during blooms keep people from swimming, boating,  
23 and otherwise enjoying the aesthetic value of lakes (S7.3.2).

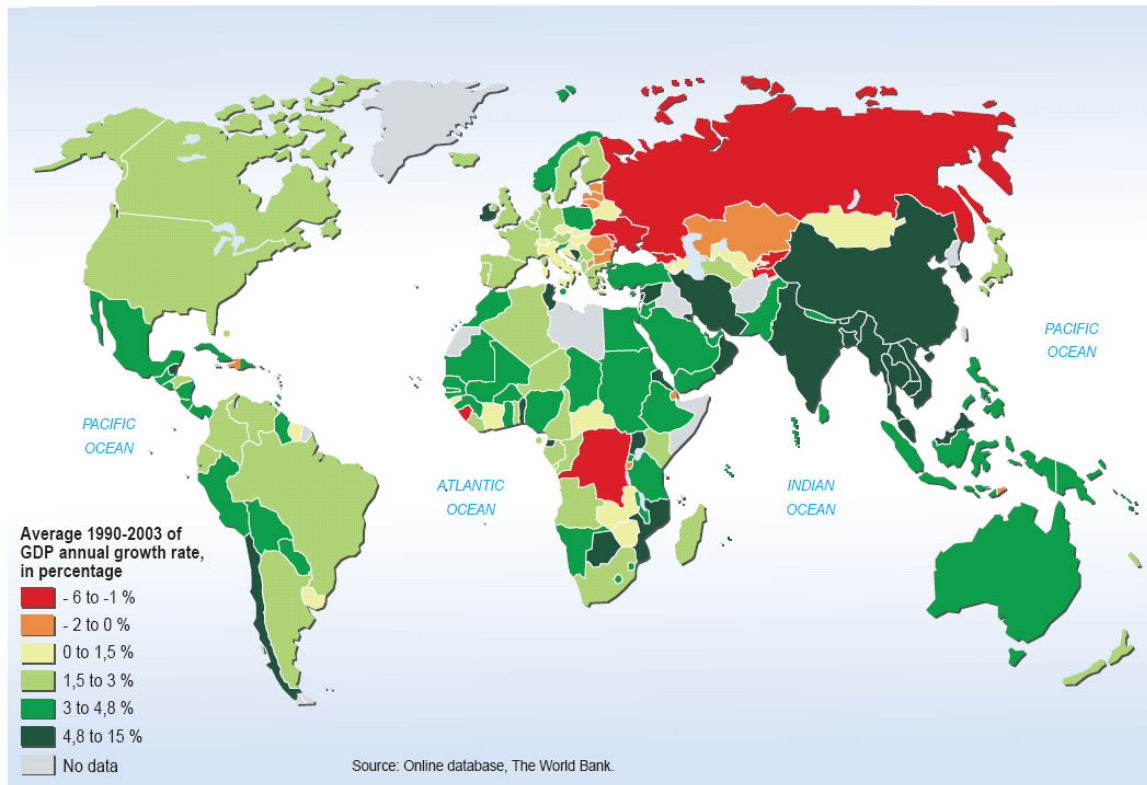

24 **Climate change in the past century has already had a measurable impact on**  
25 **ecosystems.** Earth's climate system has changed since the preindustrial era, in part due to  
26 human activities, and it is projected to continue to change throughout the twenty-first  
27 century. During the last 100 years, the global mean surface temperature has increased by  
28 about 0.6° Celsius, precipitation patterns have changed spatially and temporally, and  
29 global average sea level rose by 0.1–0.2 meters (S7.ES). Observed changes in climate,  
30 especially warmer regional temperatures, have already affected biological systems in  
31 many parts of the world. There have been changes in species distributions, population  
32 sizes, and the timing of reproduction or migration events, as well as an increase in the  
33 frequency of pest and disease outbreaks, especially in forested systems. The growing  
34 season in Europe has lengthened over the last 30 years (R13.1.3). Although it is not  
35 possible to determine whether the extreme temperatures were a result of human-induced  
36 climate change, many coral reefs have undergone major, although often partially  
37 reversible, bleaching episodes when sea surface temperatures have increased by 1°  
38 Celsius during a single season. Extensive coral mortality has occurred with observed local  
39 increases in temperature of 3° Celsius (R13.1.3).

1 **Table 4.1. Increase in Nitrogen Fluxes in Rivers to Coastal Oceans due to Human**  
 2 **Activities Relative to Fluxes Prior to the Industrial and Agricultural Revolutions (R9**  
 3 **Table 9.1)**

Labrador & Hudson's Bay	no change
Southwestern Europe	3.7-fold
Great Lakes/St. Lawrence basin	4.1-fold
Baltic Sea watersheds	5.0-fold
Mississippi River basin	5.7-fold
Yellow River basin	10-fold
Northeastern US	11-fold
North Sea watersheds	15-fold
Republic of Korea	17-fold

5 **Figure 4.1. GDP Average Annual Growth, 1990–2003 (S7 Fig 7.6).** Average annual  
 6 percentage growth rate of GDP at market prices based on constant local currency. Dollar  
 7 figures for GDP are converted from domestic currencies using 1995 official exchange  
 8 rates. GDP is the sum of gross value added by all resident producers in the economy plus  
 9 any product taxes and minus any subsidies not included in the value of the products. It is  
 10 calculated without making deductions for depreciation of fabricated assets or for  
 11 depletion and degradation of natural resources.

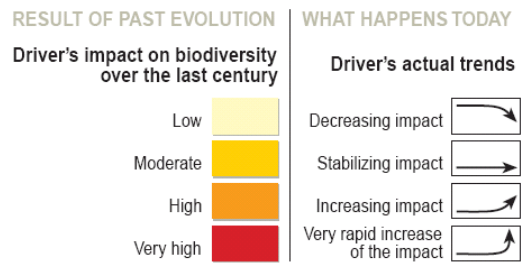

12

1 **Figure 4.2. Per capita GDP Average Annual Growth, 1990–2003 (S7 Fig 7.6).**  
2 Average annual percentage growth rate of GDP per capita at market prices based on  
3 constant local currency. Dollar figures for GDP are converted from domestic currencies  
4 using 1995 official exchange rates. GDP is the sum of gross value added by all resident  
5 producers in the economy plus any product taxes and minus any subsidies not included in  
6 the value of the products. It is calculated without making deductions for depreciation of  
7 fabricated assets or for depletion and degradation of natural resources.

8

1 **Figure 4.3. Main Direct Drivers of Change in Biodiversity and Ecosystems.** The cell  
 2 color indicates impact of each driver on biodiversity in each biome over the past 50–100  
 3 years. High impact means that over the last century the particular driver has significantly  
 4 altered biodiversity in that biome; low impact indicates that it has had little influence on  
 5 biodiversity in the biome. The arrows indicate the trend in the driver. Horizontal arrows  
 6 indicate stabilization of the impact; diagonal and vertical arrows indicate progressively  
 7 stronger increasing trends in impact. Thus a vertical arrow indicates that the effect of the  
 8 driver on biodiversity is currently growing stronger. [Note: invasive species column in  
 9 draft figure below will be corrected as follows: Temperate grassland: change to  
 10 moderate impact; Temperate grassland, Desert, Island, Mountain: change arrow to  
 11 horizontal.]

## 5. How might ecosystems and their services change in the future under various plausible scenarios?

The MA developed four global scenarios to explore plausible futures for ecosystems and human well-being. (See Box 5.1.) The scenarios were developed with a focus on conditions in 2050, although they include some information through the end of the century. They explored two global development paths, one in which the world becomes increasingly globalized and the other in which it becomes increasingly regionalized, as well as two different approaches to ecosystem management, one in which actions are reactive and most problems are addressed only after they become obvious and the other in which ecosystem management is proactive and policies deliberately seek to maintain ecosystem services for the long term:

- *Global Orchestration*: This scenario depicts a globally connected society that focuses on global trade and economic liberalization and takes a reactive approach to ecosystem problems but that also takes strong steps to reduce poverty and inequality and to invest in public goods such as infrastructure and education.
- *Order from Strength*: This scenario represents a regionalized and fragmented world that is concerned with security and protection, emphasizes primarily regional markets, pays little attention to public goods, and takes a reactive approach to ecosystem problems.
- *Adapting Mosaic*: In this scenario, regional watershed-scale ecosystems are the focus of political and economic activity. Local institutions are strengthened and local ecosystem management strategies are common; societies develop a strongly proactive approach to the management of ecosystems.
- *TechnoGarden*: This scenario depicts a globally connected world relying strongly on environmentally sound technology, using highly managed, often engineered, ecosystems to deliver ecosystem services, and taking a proactive approach to the management of ecosystems in an effort to avoid problems.

**The scenarios are not predictions; instead, they were developed to explore the unpredictable and uncontrollable features of change in ecosystem services and a number of socioeconomic factors.** No scenario represents business as usual, although all begin from current conditions and trends. The future will represent a mix of approaches and consequences described in the scenarios, as well as events and innovations that have not yet been imagined. No scenario will match the future as it actually occurs. These four scenarios were not designed to explore the entire range of possible futures for ecosystem services—other scenarios could be developed with either more optimistic or more pessimistic outcomes for ecosystems, their services, and human well-being.

The scenarios were developed using both quantitative models and qualitative analysis. For some drivers (such as economic growth, land use change, and carbon emissions) and some ecosystem services (such as water withdrawals and food production), quantitative projections were calculated using established, peer-reviewed global models. Other drivers (such as rates of technological change), ecosystem services (particularly supporting and cultural services such as soil formation and recreational opportunities), and human well-being indicators (such as human health and social relations), for which there are no

1 appropriate global models, were estimated qualitatively. In general, the quantitative  
2 models used for these scenarios addressed incremental changes but failed to address  
3 thresholds, risk of extreme events, or impacts of large, extremely costly, or irreversible  
4 changes in ecosystem services. These phenomena were addressed qualitatively, by  
5 considering the risks and impacts of large but unpredictable ecosystem changes in each  
6 scenario.

### 7 *Projected Changes in Indirect and Direct Drivers under MA Scenarios*

8 **In the four MA scenarios, during the first half of the twenty-first century the array**  
9 **of both indirect and direct drivers affecting ecosystems and their services is**  
10 **projected to remain largely the same as over the last half-century, but the relative**  
11 **importance of different drivers will begin to change.** Some factors (such as global  
12 population growth) will begin to decline in importance and others (distribution of people,  
13 climate change, and changes to nutrient cycles) will gain more importance. (See Tables  
14 5.1, 5.2, and 5.3.)

15 Statements of certainty associated with findings related to the MA scenarios are  
16 conditional statements; they refer to level of certainty or uncertainty in the particular  
17 projection should that scenario and its associated changes in drivers unfold. They do not  
18 indicate the likelihood that any particular scenario and its associated projection will come  
19 to pass. With that caveat in mind, the four MA scenarios describe these changes between  
20 2000 and 2050 (or in some cases 2100):

- 21 ▪ *Population is projected to grow to 8.1–9.6 billion in 2050 (medium to high certainty)*  
22 *and to 6.8–10.5 billion in 2100, depending on the scenario (S7.2.1).* (See Figure 5.1.)  
23 The rate of global population growth has already peaked, at 2.1% per year in the late  
24 1960s, and had fallen to 1.35% per year in 2000, when global population reached 6  
25 billion (S7.ES). Population growth over the next several decades is expected to be  
26 concentrated in the poorest, urban communities in sub-Saharan Africa, South Asia,  
27 and the Middle East (S7.ES).
- 28 ▪ *Per capita income is projected to increase two- to fourfold, depending on the scenario*  
29 *(low to medium certainty) (S7.2.2).* Gross World Product is projected to increase  
30 roughly three to sixfold in the different scenarios. Increasing income leads to  
31 increasing per capita consumption in most parts of the world for most resources and it  
32 changes the structure of consumption. For example, diets tend to become higher in  
33 animal protein as income rises.
- 34 ▪ *Land use change (primarily the continuing expansion of agriculture) is projected to*  
35 *continue to be a major direct driver of change in terrestrial and freshwater*  
36 *ecosystems (medium to high certainty) (S9.ES).* At the global level and across all  
37 scenarios, land use change is projected to remain the dominant driver of biodiversity  
38 change in terrestrial ecosystems, consistent with the pattern over the past 50 years,  
39 followed by changes in climate and nitrogen deposition (S10.ES). However, other  
40 direct drivers may be more important than land use change in particular biomes. For  
41 example, climate change is likely to be the dominant driver of biodiversity change in  
42 tundra and deserts. Species invasions and water extraction are important drivers for  
43 freshwater ecosystems.

1     ▪ *Nutrient loading is projected to become an increasingly severe problem, particularly*  
2 *in developing countries.* Nutrient loading already has major adverse effects on  
3 freshwater ecosystems and coastal regions in both industrial and developing countries.  
4 These impacts include toxic algae blooms, other human health problems, fish kills,  
5 and damage to habitats such as coral reefs. The MA scenarios project that the global  
6 flux of nitrogen to coastal ecosystems will increase by 10–20% by 2030 (*medium*  
7 *certainty*) (S9.3.7.2). (See Figure 5.2.) River nitrogen will not change in most  
8 industrial countries, while a 20–30% increase is projected for developing countries,  
9 particularly in Asia.

10    ▪ *Climate change and its impacts (such as sea level rise) are projected to have an*  
11 *increasing effect on biodiversity and ecosystem services (medium certainty)* (S9.ES).  
12 Under the four MA scenarios, global temperature is expected to increase  
13 significantly—1.5–2.0° Celsius above preindustrial level in 2050 and 2.0–3.5° Celsius  
14 above it in 2100, depending on the scenario and using median estimates for climate  
15 change variables (*medium certainty*). This is in the low to middle range of the  
16 scenarios developed for the IPCC Third Assessment Report (2.0–6.4° Celsius), largely  
17 due to the fact that the MA scenarios with high population and economic growth are  
18 also scenarios in which significant action is taken to address the problem of climate  
19 change by mid-century. The scenarios project an increase in global average  
20 precipitation (*medium certainty*), but some areas will become more arid while others  
21 will become more moist. Climate change will directly alter ecosystem services, for  
22 example, by causing changes in the productivity and growing zones of cultivated and  
23 noncultivated vegetation. It is also projected to change the frequency of extreme  
24 events, with associated risks to ecosystem services. Finally, it is projected to  
25 indirectly affect ecosystem services in many ways, such as by causing sea level to  
26 rise, which threatens mangroves and other vegetation that now protect shorelines.

27     Climate change is projected to further adversely affect key development challenges,  
28 including providing clean water, energy services, and food; maintaining a healthy  
29 environment; and conserving ecological systems, their biodiversity, and their  
30 associated ecological goods and services (R13.1.3).

- 31     ○ Climate change is projected to exacerbate the loss of biodiversity and increase the  
32 risk of extinction for many species, especially those already at risk due to factors  
33 such as low population numbers, restricted or patchy habitats, and limited climatic  
34 ranges (*medium to high certainty*).
- 35     ○ Water availability and quality are projected to decrease in many arid and semiarid  
36 regions (*high certainty*).
- 37     ○ The risk of floods and droughts is projected to increase (*high certainty*).
- 38     ○ The reliability of hydropower and biomass production is projected to decrease in  
39 some regions (*high certainty*).
- 40     ○ The incidence of vector-borne diseases such as malaria and dengue and of  
41 waterborne diseases such as cholera is projected to increase in many regions  
42 (*medium to high certainty*), and so too are heat stress mortality and threats of  
43 decreased nutrition in other regions, along with severe weather traumatic injury  
44 and death (*high certainty*).
- 45     ○ Agricultural productivity is projected to decrease in the tropics and sub-tropics for  
46 almost any amount of warming (*low to medium certainty*), and there are projected  
47 adverse effects on fisheries.

- 1       ○ Projected changes in climate during the twenty-first century are very likely to be  
2       without precedent during at least the past 10,000 years and, combined with land  
3       use change and the spread of exotic or alien species, are likely to limit both the  
4       capability of species to migrate and the ability of species to persist in fragmented  
5       habitats.
- 6
- 7       ▪ *By the end of the century, climate change and its impacts may be the dominant direct*  
8       *drivers of biodiversity loss and the change in ecosystem services globally (R13).*  
9       Harm to biodiversity will grow with both increasing rates in change in climate and  
10      increasing absolute amounts of change. For ecosystem services, some services in  
11      some regions may initially benefit from increases in temperature or precipitation  
12      expected under climate scenarios, but the balance of evidence suggests that there will  
13      be a significant net harmful impact on ecosystem services worldwide if global mean  
14      surface temperature increases more than 2° Celsius above preindustrial levels or at  
15      rates greater than 0.2° Celsius per decade (*medium certainty*).

16      This judgment is based on the evidence that an increase of about 2° Celsius above  
17      preindustrial levels in global mean surface temperature would represent a transition  
18      between the negative effects of climate change being felt in only some regions of the  
19      world to most regions of the world. For example, below an increase of about 2°  
20      Celsius, agricultural productivity is projected to be adversely affected in the tropics  
21      and sub-tropics, but beneficially affected in most temperate and high-latitude regions,  
22      whereas more warming than that is projected to have adverse impacts on agricultural  
23      productivity in many temperate regions. A 2° increase would have both positive and  
24      negative economic impacts, but most people would be adversely affected—that is,  
25      there would be predominantly negative economic effects in developing countries. It  
26      would pose a risk to many unique and threatened ecological systems and lead to the  
27      extinction of numerous species. And it would lead to a significant increase in extreme  
28      climatic events and adversely affect water resources in countries that are already  
29      water-scarce or water-stressed and would affect human health and property.

30      ***Changes in Ecosystems***

31      **Rapid conversion of ecosystems is projected to continue under all MA scenarios in**  
32      **the first half of the twenty-first century.** Roughly 10–20% (*low to medium certainty*) of  
33      current grassland and forestland is projected to be converted to other uses between now  
34      and 2050, mainly due to the expansion of agriculture and, secondarily, because of the  
35      expansion of cities and infrastructure (S9.ES). The biomes projected to lose habitat and  
36      local species at the fastest rate in the next 50 years are warm mixed forests, savannas,  
37      scrub, tropical forests, and tropical woodlands (S10ES). Rates of conversion of  
38      ecosystems are highly dependent on future development scenarios and in particular on  
39      changes in population, wealth, and technology.

40      **Habitat loss in terrestrial environments is projected to accelerate decline in local**  
41      **diversity of native species in all four scenarios by 2050** (*high certainty*) (S.SDM). Loss  
42      of habitat results in the immediate extirpation of local populations and the loss of the  
43      services that these populations provided.

44

45      **The habitat losses projected in the MA scenarios will lead to global extinctions as**  
46      **numbers of species approach equilibrium with the remnant habitat** (*high certainty*)

1 (S.SDM, S10.ES). The equilibrium number of plant species is projected to be reduced by  
2 roughly 10–15% as a result of habitat loss from 1970 to 2050 in the MA scenarios (*low*  
3 *certainty*). Other terrestrial taxonomic groups are likely to be affected to a similar extent.  
4 The pattern of extinction through time cannot be estimated with any precision, because  
5 some species will be lost immediately when their habitat is modified but others may  
6 persist for decades or centuries. Time lags between habitat reduction and extinction  
7 provide an opportunity for humans to deploy restoration practices that may rescue those  
8 species that otherwise may be in a trajectory toward extinction. Significant declines in  
9 freshwater fish species diversity are also projected due to the combined effects of climate  
10 change, water withdrawals, eutrophication, acidification, and increased invasions by  
11 nonindigenous species (*low certainty*). Rivers that are expected to lose fish species are  
12 concentrated in poor tropical and sub-tropical countries.

### 13 ***Changes in Ecosystem Services and Human Well-being***

14 **In three of the four MA scenarios, ecosystem services show net improvements in at**  
15 **least one of the three categories of provisioning, regulating, and cultural services**  
16 (S.SDM). These three ecosystem services are all in worse condition in 2050 than they are  
17 today in only one MA scenario—*Order from Strength*. (See Figure 5.3.) However, even  
18 in scenarios showing improvement in one or more categories of ecosystem services,  
19 biodiversity loss continues at high rates.

20 The following changes to ecosystem services and human well-being were common to all  
21 four MA scenarios and thus may be likely under a wide range of plausible futures  
22 (S.SDM):

- 23 ▪ *Human use of ecosystem services increases substantially under all MA scenarios*  
24 *during the next 50 years.* In many cases this is accompanied by degradation in the  
25 quality of the service and sometimes, in cases where the service is being used  
26 unsustainably, a reduction in the quantity of the service available. (See Appendix A.)  
27 The combination of growing populations and growing per capita consumption  
28 increases the demand for ecosystem services, including water and food. For example,  
29 demand for food crops (measured in tons) is projected to grow by 70–85% by 2050  
30 (S9.4.1) and global water withdrawals are to increase by 30–85% across the MA  
31 scenarios (S9 Fig. 9.34). Water withdrawals are projected to increase significantly in  
32 developing countries but to decline in OECD countries (*medium certainty*) (S.SDM).  
33 In some cases, this growth in demand will be met by unsustainable uses of the  
34 services, such as through continued depletion of marine fisheries. Demand is  
35 dampened somewhat by increasing efficiency in use of resources. The quantity and  
36 quality of ecosystem services will change dramatically in the next 50 years as  
37 productivity of some services is increased to meet demand, as humans use a greater  
38 fraction of some services, and as some services are diminished or degraded.  
39 Ecosystem services that are projected to be further impaired by ecosystem change  
40 include fisheries, food production in drylands, quality of fresh waters, and cultural  
41 services.
- 42 ▪ *Food security is likely to remain out of reach for many people.* Child malnutrition will  
43 be difficult to eradicate even by 2050 (*low to medium certainty*) and is projected to  
44 increase in some regions in some MA scenarios, despite increasing food supply under  
45 all four scenarios (*medium to high certainty*) and more diversified diets in poor

1 countries (*low to medium certainty*) (S.SDM). This is due to a combination of factors  
2 related to food supply systems (inadequate investments in food production and its  
3 supporting infrastructure resulting in low productivity increases, varying trade  
4 regimes) and food demand and accessibility (continuing poverty in combination with  
5 high population growth rates, lack of food infrastructure investments).  
6

- 7 ▪ *Vast, complex changes with great geographic variability are projected to occur in*  
8 *world freshwater resources and hence in their provisioning of ecosystem services in*  
9 *all scenarios* (S.SDM). Climate change will lead to increased precipitation over more  
10 than half of Earth's surface, and this will make more water available to society and  
11 ecosystems (*medium certainty*). However, increased precipitation is also likely to  
12 increase the frequency of flooding in many areas (*high certainty*). Increases in  
13 precipitation will not be universal, and climate change will also cause a substantial  
14 decrease in precipitation in some areas, with an accompanying decrease in water  
15 availability (*medium certainty*). These areas could include highly populated arid  
16 regions such as the Middle East and Southern Europe (*low to medium certainty*).  
17 While water withdrawals decrease in most industrial countries, they are expected to  
18 increase substantially in Africa and some other developing regions, along with  
19 wastewater discharges, overshadowing the possible benefits of increased water  
20 availability (*medium certainty*).  
21
- 22 ▪ *A deterioration of the services provided by freshwater resources (such as aquatic*  
23 *habitat, fish production, and water supply for households, industry, and agriculture)*  
24 *is expected in developing countries under the scenarios that are reactive to*  
25 *environmental problems* (S9.ES). Less severe but still important declines are expected  
26 in the scenarios that are more proactive about environmental problems (*medium*  
27 *certainty*).  
28
- 29 ▪ *Growing demand for fish and fish products leads to an increasing risk of a major and*  
30 *long-lasting collapse of regional marine fisheries* (*low to medium certainty*) (S.SDM).  
31 Aquaculture may relieve some of this pressure by providing for an increasing fraction  
32 of fish demand. However, this would require aquaculture to reduce its current reliance  
33 on marine fish as a feed source.

34 **The future contribution of terrestrial ecosystems to the regulation of climate is**  
35 **uncertain** (S9.ES). Carbon release or uptake by ecosystems affects the CO<sub>2</sub> and CH<sub>4</sub>  
36 content of the atmosphere at the global scale and thereby affects global climate.  
37 Currently, the biosphere is a net sink of carbon, absorbing about 1–2 gigatons a year, or  
38 approximately 20% of fossil fuel emissions. It is very likely that the future of this service  
39 will be greatly affected by expected land use change. In addition, a higher atmospheric  
40 CO<sub>2</sub> concentration is expected to enhance net productivity, but this does not necessarily  
41 lead to an increase in the carbon sink. The limited understanding of soil respiration  
42 processes generates uncertainty about the future of the carbon sink. There is *medium*  
43 *certainty* that climate change will increase terrestrial fluxes of CO<sub>2</sub> and CH<sub>4</sub> in some  
44 regions (such as in Arctic tundra).

45 **Dryland ecosystems are particularly vulnerable to changes over the next 50 years.**  
46 The combination of low current levels of human well-being (high rates of poverty, low  
47 per capita GDP, high infant mortality rates), a large and growing population, high  
48 variability of environmental conditions in dryland regions, and high sensitivity of people

1 to changes in ecosystem services means that continuing land degradation could have  
2 profoundly negative impacts on the well-being of a large number of people in these  
3 regions (S.SDM). Subsidies of food and water to people in vulnerable drylands can have  
4 the unintended effect of increasing the risk of even larger breakdowns of ecosystem  
5 services in future years. Local adaptation and conservation practices can mitigate some  
6 losses of dryland ecosystem services, although it will be difficult to reverse trends toward  
7 loss of food production capacity, water supplies, and biodiversity in drylands.

8  
9 **While human health improves under most MA scenarios, under one plausible future**  
10 **health and social conditions in the North and South could diverge** (S11). In the more  
11 promising scenarios related to health, the number of undernourished children is reduced,  
12 the burden of epidemic diseases such as HIV/AIDS, malaria, and tuberculosis would be  
13 lowered, improved vaccine development and distribution could allow populations to cope  
14 comparatively well with the next influenza pandemic, and the impact of other new  
15 diseases such as SARS would also be limited by well-coordinated public health measures.

16 Under the *Order from Strength* scenario, however, it is plausible that the health and social  
17 conditions for the North and South could diverge as inequality increases and as commerce  
18 and scientific exchanges between industrial and developing countries decrease. In this  
19 case, health in developing countries could become worse, causing a negative spiral of  
20 poverty, declining health, and degraded ecosystems. The increased population in the  
21 South, combined with static or deteriorating nutrition, could force increased contact  
22 between humans and nonagricultural ecosystems, especially to obtain bushmeat and other  
23 forest goods. This could lead to more outbreaks of hemorrhagic fever and zoonoses. It is  
24 possible, though with low probability, that a more chronic disease could cross from a  
25 nondomesticated animal species into humans, at first slowly but then more rapidly  
26 colonizing human populations, as HIV is thought to have done.

27 **Each scenario yields a different package of gains, losses, and vulnerabilities to**  
28 **components of human well-being in different regions and populations** (S.SDM). (See  
29 Table 5.4.) Actions that focus on improving the lives of the poor by reducing barriers to  
30 international flows of goods, services, and capital tend to lead to the most improvement in  
31 health and social relations for the currently most disadvantaged people. But human  
32 vulnerability to ecological surprises is high. Globally integrated approaches that focus on  
33 technology and property rights for ecosystem services generally improve human well-  
34 being in terms of health, security, social relations, and material needs. If the same  
35 technologies are used globally, however, local culture can be lost or undervalued. High  
36 levels of trade lead to more rapid spread of emergent diseases, somewhat reducing the  
37 gains in health in all areas. Locally focused, learning-based approaches lead to the largest  
38 improvements in social relations.

39 *Order from Strength*, which focuses on reactive policies in a regionalized world, has the  
40 least favorable outcomes for human well-being, as the global distribution of ecosystem  
41 services and human resources that underpin human well-being are increasingly skewed.  
42 Wealthy populations generally meet most material needs but experience psychological  
43 unease. Anxiety, depression, obesity, and diabetes have a greater impact on otherwise  
44 privileged populations in this scenario. Disease creates a heavy burden for disadvantaged  
45 populations.

46 **Proactive or anticipatory management of ecosystems is generally advantageous in**  
47 **the MA scenarios, but it is particularly beneficial under conditions of changing or**

1 **novel conditions** (S.SDM). Ecological surprises are inevitable because of the complexity  
2 of the interactions and because of limitations in current understanding of the dynamic  
3 properties of ecosystems. Currently well understood phenomena that were surprises of the  
4 past century include the ability of pests to evolve resistance to biocides, the contribution  
5 to desertification of certain types of land use, biomagnification of toxins, and the increase  
6 in vulnerability of ecosystem to eutrophication and unwanted species due to removal of  
7 predators. While we do not know which surprises lie ahead in the next 50 years, we can  
8 be certain that there will be some.

9 In general, proactive action to manage systems sustainably and to build resilience into  
10 systems will be advantageous, particularly when conditions are changing rapidly, when  
11 surprise events are likely, or when uncertainty is high. This approach is beneficial largely  
12 because the restoration of ecosystems or ecosystem services following their degradation  
13 or collapse is generally more costly and time-consuming than preventing degradation, if  
14 that is possible at all. Nevertheless, there are costs and benefits to both proactive and  
15 reactive approaches, as Table 5.1 indicated.

## Box 5.1. MA Scenarios

1  
2  
3

4 The *Global Orchestration* scenario depicts a globally connected society in which policy reforms that focus on global trade and economic liberalization are used to reshape economies and governance, emphasizing the creation of markets that allow equal participation and provide equal access to goods and services. These policies, in combination with large investments in global public health and the improvement of education worldwide, generally succeed in promoting economic expansion and lifting many people out of poverty into an expanding global middle class. Supra-national institutions in

13 this globalized scenario are well placed to deal with global  
14 environmental problems such as climate change and fisheries decline. However, the reactive  
15 approach to ecosystem management makes people vulnerable to surprises arising from delayed  
16 action. While the focus is on improving the well-being of all people, environmental problems that  
17 threaten human well-being are only considered after they become apparent.

18  
19 Growing economies, expansion of education, and growth of the middle class lead to demands for  
20 cleaner cities, less pollution, and a more beautiful environment. Rising income levels bring about  
21 changes in global consumption patterns, boosting demand for ecosystem services, including  
22 agricultural products such as meat, fish, and vegetables. Growing demand for these services leads  
23 to declines in other ones, as forests are converted into cropped area and pasture and the services  
24 they formerly provided decline. The problems related to increasing food production, such as loss  
25 of wildlands, are not apparent to most people who live in urban areas. They therefore receive only  
26 limited attention.

27  
28 Global economic expansion expropriates or degrades many of the ecosystem services poor people  
29 once depended on for survival. While economic growth more than compensates for these losses in  
30 some regions by increasing the ability to find substitutes for particular ecosystem services, in  
31 many other places, it does not. An increasing number of people are affected by the loss of basic  
32 ecosystem services essential for human life. While risks seem manageable in some places, in  
33 other places there are sudden, unexpected losses as ecosystems cross thresholds and degrade  
34 irreversibly. Loss of potable water supplies, crop failures, floods, species invasions, and outbreaks  
35 of environmental pathogens increase in frequency. The expansion of abrupt, unpredictable  
36 changes in ecosystems, many with harmful effects on increasingly large numbers of people, is the  
37 key challenge facing managers of ecosystem services.

38  
39 The *Order from Strength* scenario represents a regionalized and  
40 fragmented world that is concerned with security and protection,  
41 emphasizes primarily regional markets, and pays little attention to  
42 common goods. Nations see looking after their own interests as the  
43 best defense against economic insecurity, and the movement of  
44 goods, people, and information is strongly regulated and policed. The  
45 role of government expands as oil companies, water utilities, and  
46 other strategic businesses are either nationalized or subjected to more  
47 state oversight. Trade is restricted, large amounts of money are  
48 invested in security systems, and technological change slows due to restrictions on the flow of  
49 goods and information. Regionalization exacerbates global inequality.

50  
51 Treaties on global climate change, international fisheries, and trade in endangered species are only  
52 weakly and haphazardly implemented, resulting in degradation of the global commons. Local  
53 problems often go unresolved, but major problems are sometimes handled by rapid disaster relief  
54 to at least temporarily resolve the immediate crisis. Many powerful countries cope with local  
55 problems by shifting burdens to other, less powerful ones, increasing the gap between rich and

1 poor. In particular, natural resource-intensive industries are moved from wealthier nations to  
2 poorer, less powerful ones. Inequality increases considerably within countries as well.

3  
4 Ecosystem services become more vulnerable, fragile, and variable in *Order from Strength*. For  
5 example, parks and reserves exist within fixed boundaries, but climate changes around them,  
6 leading to the unintended extirpation of many species. Conditions for crops are often suboptimal,  
7 and the ability of societies to import alternative foods is diminished by trade barriers. As a result,  
8 there are frequent shortages of food and water, particularly in poor regions. Low levels of trade  
9 tend to restrict the number of invasions by exotic species; ecosystems are less resilient, however,  
10 and invaders are therefore more often successful when they arrive.

11  
12 In the *Adapting Mosaic* scenario, regional watershed-scale ecosystems  
13 are the focus of political and economic activity. This scenario sees the  
14 rise of local ecosystem management strategies and the strengthening of  
15 local institutions. Investments in human and social capital are geared  
16 toward improving knowledge about ecosystem functioning and  
17 management, which results in a better understanding of resilience,  
18 fragility, and local flexibility of ecosystems. There is optimism that we  
19 can learn, but humility about preparing for surprises and about our  
20 ability to know everything about managing ecosystems.

21  
22 There is also great variation among nations and regions in styles of governance, including  
23 management of ecosystem services. Some regions explore actively adaptive management,  
24 investigating alternatives through experimentation. Others use bureaucratically rigid methods to  
25 optimize ecosystem performance. Great diversity exists in the outcome of these approaches: some  
26 areas thrive, while others develop severe inequality or experience ecological degradation.  
27 Initially, trade barriers for goods and products are increased, but barriers for information nearly  
28 disappear (for those who are motivated to use them) due to improving communication  
29 technologies and rapidly decreasing costs of access to information.

30  
31 Eventually, the focus on local governance leads to failures in managing the global commons.  
32 Problems like climate change, marine fisheries, and pollution grow worse, and global  
33 environmental problems intensify. Communities slowly realize that they cannot manage their  
34 local areas because global and regional problems are infringing on them, and they begin to  
35 develop networks among communities, regions, and even nations to better manage the global  
36 commons. Solutions that were effective locally are adopted among networks. These networks of  
37 regional successes are especially common in situations where there are mutually beneficial  
38 opportunities for coordination, such as along river valleys. Sharing good solutions and discarding  
39 poor ones eventually improves approaches to a variety of social and environmental problems,  
40 ranging from urban poverty to agricultural water pollution. As more knowledge is collected from  
41 successes and failures, provision of many services improves.

42  
43 The *TechnoGarden* scenario depicts a globally connected world  
44 relying strongly on technology and highly managed, often  
45 engineered ecosystems to deliver ecosystem services. Overall  
46 efficiency of ecosystem service provision improves, but it is  
47 shadowed by the risks inherent in large-scale humanmade solutions  
48 and rigid control of ecosystems. Technology and market-oriented  
49 institutional reform are used to achieve solutions to environmental  
50 problems. These solutions are designed to benefit both the economy  
51 and the environment. These changes co-develop with the expansion  
52 of property rights to ecosystem services, such as requiring people to  
53 pay for pollution they create or paying people for providing key ecosystem services through  
54 actions such as preservation of key watersheds. Interest in maintaining, and even increasing, the  
55 economic value of these property rights, combined with an interest in learning and information,

1 leads to a flowering of ecological engineering approaches for managing ecosystem services.  
2 Investment in green technology is accompanied by a significant focus on economic development  
3 and education, improving people's lives and helping them understand how ecosystems make their  
4 livelihoods possible.

5  
6 A variety of problems in global agriculture are addressed by focusing on the multifunctional  
7 aspects of agriculture and a global reduction of agricultural subsidies and trade barriers.  
8 Recognition of the role of agricultural diversification encourages farms to produce a variety of  
9 ecological services rather than simply maximizing food production. The combination of these  
10 movements stimulates the growth of new markets for ecosystem services, such as tradable  
11 nutrient runoff permits, and the development of technology for increasingly sophisticated  
12 ecosystem management. Gradually, environmental entrepreneurship expands as new property  
13 rights and technologies co-evolve to stimulate the growth of companies and cooperatives  
14 providing reliable ecosystem services to cities, towns, and individual property owners.

15  
16 Innovative capacity expands quickly in developing nations. The reliable provision of ecosystem  
17 services as a component of economic growth, together with enhanced uptake of technology due to  
18 rising income levels, lifts many of the world's poor into a global middle class. Elements of human  
19 well-being associated with social relations decline in this scenario due to great loss of local  
20 culture, customs, and traditional knowledge and the weakening of civil society institutions as an  
21 increasing share of interactions take place over the Internet. While the provision of basic  
22 ecosystem services improves the well-being of the world's poor, the reliability of the services,  
23 especially in urban areas, become more critical and is increasingly difficult to ensure. Not every  
24 problem has succumbed to technological innovation. Reliance on technological solutions  
25 sometimes creates new problems and vulnerabilities. In some cases, societies seem to be barely  
26 ahead of the next threat to ecosystem services. In such cases new problems often seem to emerge  
27 from the last solution, and the costs of managing the environment are continually rising.  
28 Environmental breakdowns that affect large numbers of people become more common.  
29 Sometimes new problems seem to emerge faster than solutions. The challenge for the future is to  
30 learn how to organize socioecological systems so that ecosystem services are maintained without  
31 taxing society's ability to implement solutions to novel, emergent problems.  
32

1 **Table 5.1. Main Assumptions Concerning Indirect and Direct Driving Forces Used**  
 2 **in the MA Scenarios (S.SDM)** (“Industrialized” and “developing” nations refer to the  
 3 countries at the beginning of the scenario; some may change by 2050.)  
 4

	Global Orchestration	Order from Strength		Adapting Mosaic	TechnoGarden
		Industrialized Nations	Developing Nations		
<b>Indirect Drivers</b>					
<b>Demographics</b>	high migration; low fertility and mortality levels  2050 population: 8.1 billion	high fertility and mortality levels (esp. in developing countries); low migration  2050 population: 9.6 billion		high fertility level; high mortality levels until 2010 then to medium by 2050; low migration 2050 population: 9.5 billion	medium fertility and mortality levels; medium migration  2050 population: 8.8 billion
<b>Average income growth</b>	high	medium	low	similar to <i>Order from Strength</i> but with increasing growth rates toward 2050	lower than <i>Global Orchestration</i> , but catching up toward 2050
<b>GDP growth rates/capita per year until 2050</b>	Global: 1995- 2020: 2.4 % per year 2020-2050: 3.0%/ per ear	1995-2020: 1.4 % per year 2020-2050: 1.0 % per year		1995-2020: 1.5 % per year 2020-2050: 1.9 % per year	1995-2020: 1.9 % per year 2020-2050: 2.5 % per year
	industrialized c.: 1995-2020: 3.2 % per year 2020-2050: 2.1 % per year developing c.: 1995-2020: 4.8 % per year 2020-2050: 4.8 % per year	1995-2020: 2.6 % per year 2020-2050: 1.4 % per year	1995-2020: 3.0 % per year 2020-2050: 2.3 % per year	industrialized c.: 1995- 2020: 2.6 % per year 2020-2050: 1.7 % per year developing c.: 1995-2020: 3.5 % per year 2020-2050: 3.5 % per year	industrialized c.: 1995-2020: 2.9 % per year 2020-2050: 1.9 % per year developing c.: 1995-2020: 4.0 % per year 2020-2050: 4.3 % per year
<b>Income distribution</b>	becomes more equal	similar to today		similar to today, then becomes more equal	becomes more equal
<b>Investments into new produced assets</b>	high	medium	low	begins like <i>Order from Strength</i> , then increases in tempo	high
<b>Investments into human capital</b>	high	medium	low	begins like <i>Order from Strength</i> , then increases in tempo	medium
<b>Overall trend in technology advances</b>	high	low		medium-low	medium in general; high for environmental technology
<b>International cooperation</b>	strong	weak - international competition		weak - focus on local environment	strong
<b>Attitude toward environmental policies</b>	reactive	reactive		proactive - learning	proactive
<b>Energy demand and lifestyle</b>	Energy-intensive	regionalized assumptions		regionalized assumptions	high level of energy efficiency; saturation in energy use
<b>Energy supply</b>	market liberalization; selects least-cost options; rapid	focus on domestic energy resources		some preference for clean energy resources	preference for renewable energy resources and rapid technology change

	Global Orchestration	Order from Strength		Adapting Mosaic	TechnoGarden
		Industrialized Nations	Developing Nations		
	technology change				
<b>Climate policy</b>	no	no		no	yes, aims at stabilization of CO <sub>2</sub> - equivalent concentration at 550 ppmv
<b>Approach to achieving sustainability</b>	economic growth leads to sustainable development	national-level policies; conservation; reserves, parks		local-regional co- management; common- property institutions	green-technology; eco-efficiency; tradable ecological property rights
<b>Direct Drivers</b>					
<b>Land use change</b>	global forest loss until 2025 slightly below historic rate, stabilizes after 2025; ~10 % increase in arable land	global forest loss faster than historic rate until 2025; near current rate after 2025; ~20% increase in arable land compared with 2000		global forest loss until 2025 slightly below historic rate; stabilizes after 2025; ~10 % increase in arable land	net increase in forest cover globally until 2025; slow loss after 2025; ~9 % increase in arable land
<b>Greenhouse gas emissions by 2050</b>	CO <sub>2</sub> : 20.1 GtC- eq CH <sub>4</sub> : 3.7 GtC- eq N <sub>2</sub> O: 1.1 GtC- eq Other GHG: 0.7 GtC- eq	CO <sub>2</sub> : 15.4 GtC- eq CH <sub>4</sub> : 3.3 GtC- eq N <sub>2</sub> O: 1.1 GtC- eq Other GHG: 0.5 GtC- eq		CO <sub>2</sub> : 13.3 GtC- eq CH <sub>4</sub> : 3.2 GtC- eq N <sub>2</sub> O: 0.9 GtC- eq Other GHG: 0.6 GtC- eq	CO <sub>2</sub> : 4.7 GtC- eq CH <sub>4</sub> : 1.6 GtC- eq N <sub>2</sub> O: 0.6 GtC- eq Other GHG: 0.2 GtC- eq
<b>Air pollution emissions</b>	SO <sub>2</sub> emissions stabilize; NO <sub>x</sub> emissions increase from 2000 to 2050	both SO <sub>2</sub> and NO <sub>x</sub> emissions increase globally		SO <sub>2</sub> emissions decline; NO <sub>x</sub> emissions increase slowly	strong reductions in SO <sub>2</sub> and NO <sub>x</sub> emissions
<b>Climate change</b>	2.0°C in 2050 and 3.5°C in 2100 above pre- industrial	1.7°C in 2050 and 3.3°C in 2100 above pre-industrial		1.9°C in 2050 and 2.8°C in 2100 above pre- industrial	1.5°C in 2050 and 1.9°C in 2100 above pre-industrial
<b>Nutrient loading</b>	increase in N transport in rivers	increase in N transport in rivers		increase in N transport in rivers	decrease in N transport in rivers

6

Sources: Millennium Ecosystem Assessment.

1 **Figure 5.3. Changes in Availability of Ecosystem Services by 2050 in the Four MA**  
 2 **Scenarios.** Figure shows the net percent change in ecosystem services enhanced  
 3 (positive) or degraded in each category of services for industrial and developing  
 4 countries. The total number of services evaluated for each category was six provisioning  
 5 services, nine regulating services, and five cultural services. [Note: Figure still draft –  
 6 percentage change for several bars incorrect.]  
 7

8 Sources: Millennium Ecosystem Assessment.

1 **6. What can be learned about the consequences of**  
2 **ecosystem change for human well-being at sub-**  
3 **global scales?**

4 **The MA included a sub-global assessment component to assess differences in the**  
5 **importance of ecosystem services for human well-being around the world (SG.SDM).**  
6 The Sub-global Working Group included 33 assessments around the world. These were  
7 designed to consider the importance of ecosystem services for human well-being at local,  
8 national, and regional scales. The areas covered in these assessments range from small  
9 villages in India and cities like Stockholm and São Paulo to whole countries like Portugal  
10 and large regions like southern Africa. In a few cases, the sub-global assessments were  
11 designed to cover multiple nested scales. For example, the Southern Africa study included  
12 assessments of the entire region of Africa south of the equator, of the Gariep and Zambezi  
13 river basins in that region, and of local communities within those basins. This nested  
14 design was included as part of the overall design of the MA to analyze the importance of  
15 scale on ecosystem services and human well-being and to study cross-scale interactions.  
16 Most assessments, however, were conducted with a focus on the needs of users at a single  
17 spatial scale—a particular community, watershed, or region.

18 **The scale at which an assessment is undertaken significantly influences the problem**  
19 **definition and the assessment results (SG.SDM).** Findings of assessments done at  
20 different scales varied due to the specific questions posed or the information analyzed.  
21 Local communities are influenced by global, regional, and local factors. Global factors  
22 include commodity prices (global trade asymmetries that influence local production  
23 patterns, for instance) and global climate change (such as sea level rise). Regional factors  
24 include water supply regimes (safe piped water in rural areas), regional climate  
25 (desertification), and geomorphological processes (soil erosion and degradation). Local  
26 factors include market access (distance to market), disease prevalence (malaria, for  
27 example), or localized climate variability (patchy thunderstorms). Assessments conducted  
28 at different scales tended to focus on drivers and impacts most relevant at each scale,  
29 yielding different but complementary findings. This provides some of the benefit of a  
30 multiscale assessment process, since each component assessment provides a different  
31 perspective on the issues addressed.

32 **Although there is overall congruence in the results from global and sub-global**  
33 **assessments for services like water and biodiversity, there are examples where local**  
34 **assessments showed the condition was either better or worse than expected from the**  
35 **global assessment (SG.SDM).** For example, the condition of water resources was  
36 significantly worse than expected in places like São Paulo and the Laguna Lake Basin in  
37 the Philippines. There were more mismatches for biodiversity than for water provisioning  
38 because the concepts and measures of biodiversity were more diverse in the sub-global  
39 assessments.

40 **Drivers of change act in very distinct ways in different regions (SG7.ES).** Though  
41 similar drivers might be present in various assessments, their interactions—and thus the  
42 processes leading to ecosystem change—differed significantly from assessment to  
43 another. For example, although the Amazon, Central Africa, and Southeast Asia in the  
44 Tropical Forest Margins assessment have the same set of individual drivers of land use  
45 change (deforestation, road construction, and pasture creation), the interactions among  
46 these drivers leading to change differ. Deforestation driven by swidden agriculture is

1 more widespread in upland and foothill zones of Southeast Asia than in other regions.  
2 Road construction by the state followed by colonizing migrant settlers, who in turn  
3 practice slash-and-burn agriculture, is most frequent in lowland areas of Latin America,  
4 especially in the Amazon Basin. Pasture creation for cattle ranching is causing  
5 deforestation almost exclusively in the humid lowland regions of mainland South  
6 America. The spontaneous expansion of smallholder agriculture and fuelwood extraction  
7 for domestic uses are important causes of deforestation in Africa.

8 **The assessments identified inequities in the distribution of the costs and benefits of**  
9 **ecosystem change, which are often displaced to other places or future generations**  
10 (SG.SDM). For example, the increase in urbanization in countries like Portugal is  
11 generating pressures on ecosystems and services in rural areas. The increase in  
12 international trade is also generating additional pressures around the world, illustrated by  
13 the cases of the mining industries in Chile and Papua New Guinea. In some situations, the  
14 costs of transforming ecosystems are simply deferred to future generations. An example  
15 reported widely across sub-global assessments in different parts of the world is tropical  
16 deforestation, which caters to current needs but leads to a reduced capacity to supply  
17 services in the future.

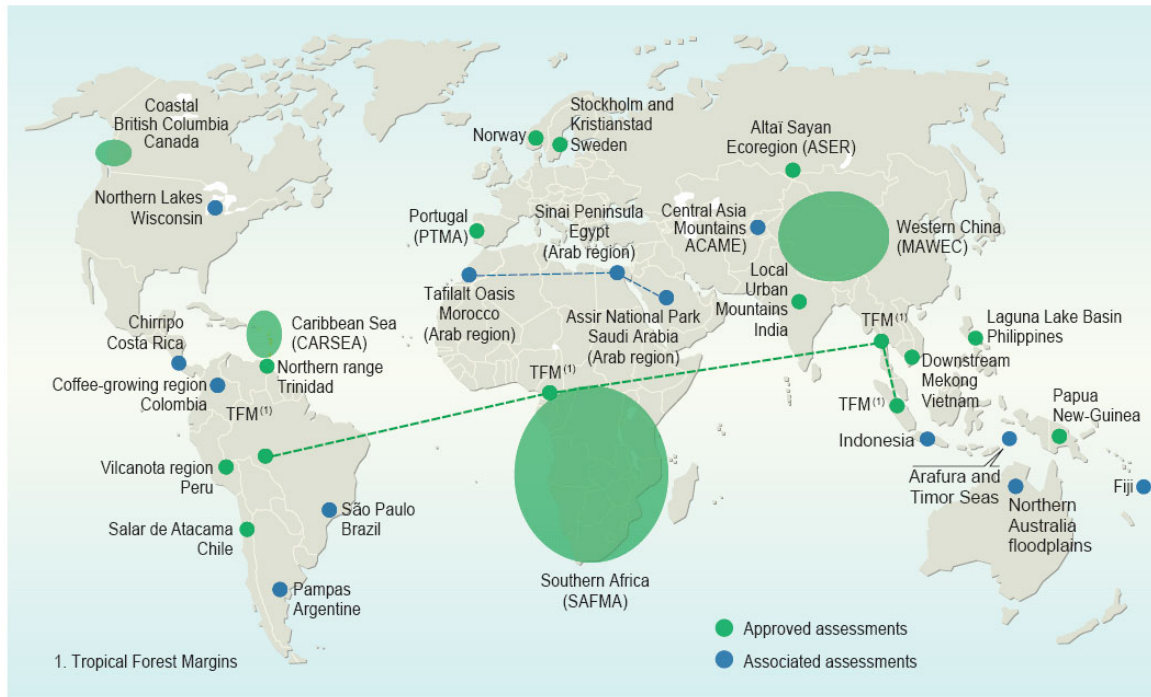

18 **Declining ecosystem trends have been mitigated by innovative local responses. The**  
19 **“threats” observed at an aggregated, global level may be both overestimated and**  
20 **underestimated from a sub-global perspective** (SG.SDM). Assessments at an  
21 aggregated level often fail to take into account the adaptive capacity of sub-global actors.  
22 Through collaboration in social networks, actors can develop new institutions and  
23 reorganize to mitigate declining conditions. On the other hand, sub-global actors tend to  
24 neglect drivers that are beyond their reach of immediate influence when they craft  
25 responses. Hence, it is crucial for decision-makers to develop institutions at the global,  
26 regional, and national levels that strengthen the adaptive capacity of actors at the sub-  
27 national and local levels to develop context-specific responses that do address the full  
28 range of relevant drivers. The Biodiversity Management Committees in India are a good  
29 example of a national institution that enables local actors to respond to biodiversity loss.  
30 This means neither centralization nor decentralization but institutions at multiple levels  
31 that enhance the adaptive capacity and effectiveness of sub-national and local responses.

32 **Multiscale assessments offer insights and results that would otherwise be missed**  
33 (SG.SDM). The variability among sub-global assessments in problem definition,  
34 objectives, scale criteria, and systems of explanation increased at finer scales of  
35 assessment (for example, social equity issues became more visible from coarser to finer  
36 scales of assessment). The role of biodiversity as a risk avoidance mechanism for local  
37 communities is frequently hidden until local assessments are conducted (as in the Indian  
38 local, Sinai, and Southern African livelihoods studies).

39 **There is evidence that including multiple knowledge systems increases the relevance,**  
40 **credibility, and legitimacy of the assessment results for some users** (SG.SDM). For  
41 example, in Bajo Chirripó in Costa Rica, the involvement of nonscientists added  
42 legitimacy and relevance to assessment results for a number of potential users at the local  
43 level. In many of the sub-global assessments, however, local resource users were one  
44 among many groups of decision-makers, so the question of legitimacy needs to be taken  
45 together with that of empowerment.

1 **Integrated assessments of ecosystems and human well-being need to be adapted to**  
2 **the specific needs and characteristics of the groups undertaking the assessment**  
3 (SG.SDM, SG11.ES). Assessments are most useful to decision-makers if they respond to  
4 the needs of those individuals. As a result, the MA sub-global assessments differed  
5 significantly in the issues they addressed. At the same time, given the diversity of  
6 assessments involved in the MA, the basic approach had to be adapted by different  
7 assessments to ensure its relevance to different user groups. (See Box 6.1.) Several  
8 community-based assessments adapted the MA framework to allow for more dynamic  
9 interplays between variables, to capture fine-grained patterns and processes in complex  
10 systems, and to leave room for a more spiritual worldview. In Peru and Costa Rica, for  
11 example, other conceptual frameworks were used that incorporated both the MA  
12 principles and local cosmologies. In southern Africa, various frameworks were used in  
13 parallel to offset the shortcomings of the MA framework for community assessments.  
14 These modifications and adaptations of the framework are an important outcome of the  
15 MA.

1 **Figure 6.1. MA Sub-Global Assessments.** Eighteen assessments were approved as  
 2 components of the MA. Any institution or country was able to undertake an assessment as  
 3 part of the MA if it agreed to use the MA Conceptual Framework, to centrally involve the  
 4 intended users as stakeholders and partners, and to meet a set of procedural requirements  
 5 related to peer review, metadata, transparency, and intellectual property rights. The MA  
 6 assessments were largely self-funded, although planning grants and some core grants  
 7 were provided to support some assessments. The MA also drew on information from 15  
 8 other sub-global assessments affiliated with the MA that met a subset of these criteria or  
 9 were at earlier stages in development.

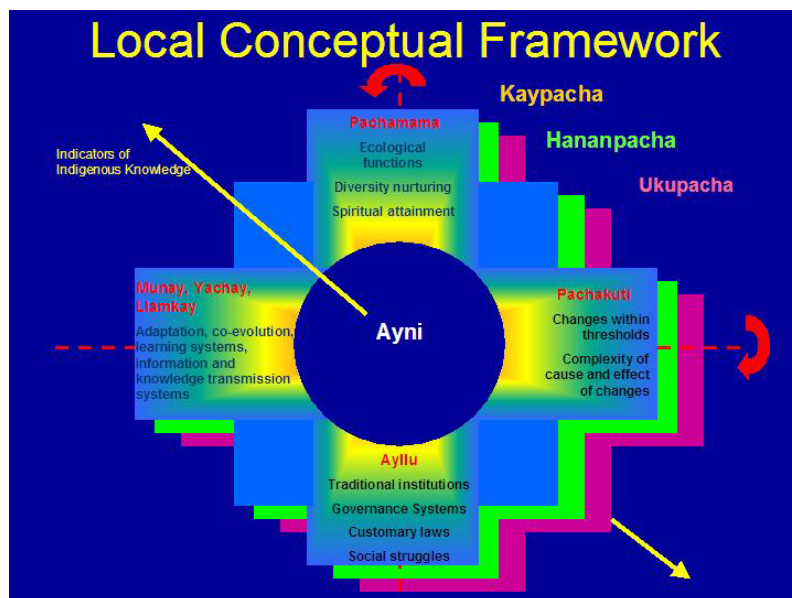

10  
 11  
 12

1 **Box 6.1 Local Adaptations of MA Conceptual Framework (SG.SDM)**

2 The MA framework was applied in a wide range of assessments at multiple scales. Particularly for  
3 the more local assessments, the framework needed to be adapted to better reflect the needs and  
4 concerns of local communities. In the case of an assessment conducted by and for indigenous  
5 communities in the Vilcanota region of Peru, the framework had to be recreated from a base with  
6 the Quechua understanding of ecological and social relationships. (See Figure.) Within the  
7 Quechua vision of the cosmos, concepts such as reciprocity (Ayni), the inseparability of space and  
8 time, and the cyclical nature of all processes (Pachakuti) are important components of the Inca  
9 definition of ecosystems. Love (Munay) and working (Llankay) bring humans to a higher state of  
10 knowledge (Yachay) about their surroundings and are therefore key concepts linking Quechua  
11 communities to the natural world. Ayllu represents the governing institutions that regulate  
12 interactions between all living beings.

13 The resulting framework has similarities with the MA Conceptual Framework, but the divergent  
14 features are considered to be important to the Quechua people conducting the assessment. The  
15 Vilcanota conceptual framework also includes multiple scales (Kaypacha, Hananpacha,  
16 Ukupacha); however, these represent both spatial scales and the cyclical relationship between the  
17 past, present, and future. Inherent in this concept of space and time is the adaptive capacity of the  
18 Quechua people, who welcome change and have become resilient to it through an adaptive  
19 learning process. (It is recognized that current rates of change may prove challenging to the  
20 adaptive capacities of the communities.) The cross shape of the Vilcanota framework diagram  
21 represents the “Chakana,” the most recognized and sacred shape to Quechua people, and orders  
22 the world through deliberative and collective decision-making that emphasizes reciprocity (Ayni).  
23 Pachamama is similar to a combination of the “ecosystem goods and services” and “human well-  
24 being” components of the MA framework. Pachakuti is similar to the MA “drivers” (both direct  
25 and indirect). Ayllu (and Munay, Yachay, and Llankay) may be seen as responses and are more  
26 organically integrated into the cyclic process of change and adaptation.

27 The Quechua communities will direct their work process to assess the conditions and trends of  
28 certain aspects of the Pachamama (focusing on water, soil, and agrobiodiversity), how these  
29 goods and services are changing, the reasons behind the changes, the effects on the other elements  
30 of the Pachamama, how the communities have adapted and are adapting to the changes, and the  
31 state of resilience of the Quechua principles and institutions for dealing with these changes in the  
32 future.

1 Developing the local conceptual framework from a base of local concepts and principles, as  
2 opposed to simply translating the MA framework into local terms, has allowed local communities  
3 to take ownership of their assessment process and given them the power both to assess the local  
4 environment and human populations using their own knowledge and principles of well-being and  
5 to seek responses to problems within their own cultural and spiritual institutions.

## 1 7. What is known about time scales, inertia, and the 2 risk of nonlinear changes in ecosystems?

3 The time scale of change refers to the time required for the effects of a perturbation of a  
4 process to be expressed. Time scales relevant to ecosystems and their services are shown  
5 in Figure 7.1. Inertia refers to the delay or slowness in the response of a system to factors  
6 altering their rate of change, including continuation of change in the system after the  
7 cause of that change has been removed. Resilience refers to the amount of disturbance or  
8 stress that a system can absorb and still remain capable of returning to its predisturbance  
9 state.

### 10 *Time Scales and Inertia*

11 **Many impacts of humans on ecosystems (both harmful and beneficial) are slow to**  
12 **become apparent; this can result in the costs associated with ecosystem changes**  
13 **being deferred to future generations.** For example, excessive phosphorus is  
14 accumulating in many agricultural soils, threatening rivers, lakes, and coastal oceans with  
15 increased eutrophication. Yet it may take years or decades for the full impact of the  
16 phosphorus to become apparent through erosion and other processes (S7.3.2). Similarly,  
17 the use of groundwater supplies can exceed the recharge rate for some time before costs  
18 of extraction begin to grow significantly. In general, people manage ecosystems in a  
19 manner that increases short-term benefits; they may not be aware of, or may ignore, costs  
20 that are not readily and immediately apparent. This has the inequitable result of increasing  
21 current benefits at costs to future generations.

22 **Different categories of ecosystem services tend to change over different time scales,**  
23 **making it difficult for managers to evaluate trade-offs fully.** For example, supporting  
24 services such as soil formation and primary production and regulating services such as  
25 water and disease regulation tend to change over much longer time scales than  
26 provisioning services. As a consequence impacts on more slowly changing supporting  
27 and regulating services are often overlooked by managers in pursuit of increased use of  
28 provisioning services (S12.ES).

29 **The inertia of various direct and indirect drivers differs considerably, and this**  
30 **strongly influences the time frame for solving ecosystem-related problems once they**  
31 **are identified** (RWG, S7). For some drivers, such as the overharvest of particular  
32 species, lag times are rather short, and the impact of the driver can be minimized or halted  
33 within short time frames. For others, such as nutrient loading and, especially, climate  
34 change, lag times are much longer, and the impact of the driver cannot be lessened for  
35 years or decades.

36 **Significant inertia exists in the process of species extinctions that result from habitat**  
37 **loss; even if habitat loss were to end today, it would take hundreds of years for**  
38 **species numbers to reach a new and lower equilibrium due to the habitat changes**  
39 **that have taken place in the last centuries** (S10). Most species that will go extinct in the  
40 next several centuries will be driven to extinction as a result of loss or degradation of their  
41 habitat (either through land cover changes or increasingly through climate changes).  
42 Habitat loss can lead to rapid extinction of some species (such as those with extremely  
43 limited ranges); but for many species, extinction will only occur after many generations,  
44 and long-lived species such as some trees could persist for centuries before ultimately

1 going extinct. This “extinction debt” has important implications. First, while reductions in  
2 the rate of habitat loss will protect certain species and have significant long-term benefits  
3 for species survival in the aggregate, the impact on rates of extinction over the next 10–50  
4 years is likely to be small (*medium certainty*). Second, until a species does go extinct,  
5 opportunities exist for it to be recovered to a viable population size.

## 6 *Nonlinear Changes in Ecosystems*

7  
8 **Nonlinear (stepped or abrupt) changes have been commonly encountered in**  
9 **ecosystems and their services.** Most of the time, change in ecosystems and their services  
10 is gradual and incremental. Most of these gradual changes are detectable and predictable,  
11 at least in principle (*high certainty*) (S.SDM). However, many examples exist of  
12 nonlinear and sometimes abrupt changes in ecosystems. In these cases, the ecosystem  
13 may change gradually until a particular pressure on it reaches a threshold, at which point  
14 changes occur relatively rapidly as the system shifts to a new state. Some of these  
15 nonlinear changes can be very large in magnitude and have substantial impacts on human  
16 well-being. Capabilities for predicting some nonlinear changes are improving, but for  
17 most ecosystems and for most potential nonlinear changes, science cannot predict the  
18 thresholds where the change will be encountered (C6.2, S13.4). Numerous examples exist  
19 of nonlinear and relatively abrupt changes in ecosystems:  
20

- 21 ▪ *Disease emergence* (S13.4): Infectious diseases regularly exhibit nonlinear behavior.  
22 If, on average, each infected person infects at least one other person, then an epidemic  
23 spreads, while if the infection is transferred on average to less than one person the  
24 epidemic dies out. High human population densities in close contact with animal  
25 reservoirs of infectious disease facilitate rapid exchange of pathogens, and if the  
26 threshold rate of infection is achieved—that is, if each infected person on average  
27 transmits the infection to at least one other person—the resulting infectious agents can  
28 spread quickly through a worldwide contiguous, highly mobile, human population  
29 with few barriers to transmission. The almost instantaneous outbreak of SARS in  
30 different parts of the world is an example of such potential, although rapid and  
31 effective action contained its spread. An event similar to the 1918 Spanish flu  
32 pandemic, which is thought to have killed 20–40 million people worldwide, could  
33 now result in over 100 million deaths within a single year. Such a catastrophic event,  
34 the possibility of which is being seriously considered by the epidemiological  
35 community, would probably lead to severe economic disruption and possibly even  
36 rapid collapse in a world economy dependent on fast global exchange of goods and  
37 services.
- 38 ▪ *Algal blooms and fish kills* (S13.4): Excessive nutrient loading fertilizes freshwater  
39 and coastal ecosystems. While small increases in nutrient loading often cause little  
40 change in many ecosystems, once a threshold of nutrient loading is achieved, the  
41 changes can be abrupt and extensive, creating harmful algal blooms (including  
42 blooms of toxic species) and often leading to the domination of the ecosystem by one  
43 or a few species. Severe nutrient overloading can lead to the formation of oxygen-  
44 depleted zones, killing all animal life.
- 45 ▪ *Fisheries collapses* (C18): Fish population collapses have been commonly  
46 encountered in both freshwater and marine fisheries. Fish populations are generally  
47 able to withstand some level of catch with a relatively small impact on their overall

1 population size. As the catch increases, however, a threshold is reached after which  
2 too few adults remain to produce enough offspring to support that level of harvest,  
3 and the population may drop abruptly to a much smaller size. For example, the  
4 Atlantic cod stocks of the east coast of Newfoundland collapsed in 1992, forcing the  
5 closure of the fishery after hundreds of years of exploitation (CF2 Box 2.4). Most  
6 important, the stocks may not recover even if harvesting is significantly reduced or  
7 eliminated entirely.

- 8     ▪ *Species introductions and losses*: Introductions (or removal) of species can cause  
9 nonlinear changes in ecosystems and their services. For example, the introduction of  
10 the zebra mussel into U.S. aquatic systems resulted in the extirpation of native clams  
11 in Lake St. Clair, large changes in energy flow and ecosystem function, and annual  
12 costs of \$100 million to the power industry and other users (S12.4.8). The  
13 introduction of the comb jelly fish (*Mnemiopsis leidyi*) in the Black Sea caused the  
14 loss of 26 major fisheries species and has been implicated (along with other factors) in  
15 subsequent growth of the anoxic “dead zone” (C28.5). The loss of the sea otters from  
16 many coastal ecosystems on the Pacific Coast of North America due to hunting led to  
17 the booming populations of sea urchins (a prey species for otters) which in turn led to  
18 the loss of kelp forests (which are eaten by urchins).
  
- 19     ▪ *Changes in dominant species in coral ecosystems*: Some coral reef ecosystems have  
20 undergone sudden shifts from coral-dominated to algae-dominated reefs. The trigger  
21 for such phase shifts, which are essentially irreversible, is usually multifaceted and  
22 includes increased nutrient input leading to eutrophic conditions, and removal of  
23 herbivorous fishes that maintain the balance between corals and algae. Once a  
24 threshold is reached, the change in the ecosystem takes place within months and the  
25 resulting ecosystem, although stable, is less productive and less diverse. One well-  
26 studied example is the sudden switch in 1983 from coral to algal domination of  
27 Jamaican reef systems. This followed several centuries of overfishing of herbivores,  
28 which left the control of algal cover almost entirely dependent on a single species of  
29 sea urchin, whose populations collapsed when exposed to a species-specific pathogen.  
30 As a result, Jamaica’s reefs shifted (apparently irreversibly) to a new low-diversity,  
31 algae-dominated state with very limited capacity to support fisheries (C4.6).
  
- 32     ▪ *Regional climate change* (C13.3): The vegetation in a region influences climate  
33 through albedo (reflectance of radiation from the surface), transpiration (flux of water  
34 from the ground to the atmosphere through plants), and the aerodynamic properties of  
35 the surface. In the Sahel region of North Africa, vegetation cover is almost completely  
36 controlled by rainfall. When vegetation is present, rainfall is quickly recycled,  
37 generally increasing precipitation and, in turn, leading to a denser vegetation canopy.  
38 Model results suggest that land degradation leads to a substantial reduction in water  
39 recycling and may have contributed to the observed trend in rainfall reduction in the  
40 region over the last 30 years. In tropical regions, deforestation generally leads to  
41 decreased rainfall. Since forest existence crucially depends on rainfall, the  
42 relationship between tropical forests and precipitation forms a positive feedback that,  
43 under certain conditions, theoretically leads to the existence of two steady states:  
44 rainforest and savanna. Some models suggest only one stable climate-vegetation state  
45 in the Amazon.

1 **There is *established but incomplete* evidence that changes being made in ecosystems**  
2 **are increasing the likelihood of nonlinear and potentially high-impact, abrupt**  
3 **changes in physical and biological systems that have important consequences for**  
4 **human well-being (C6, S3, S13.4, S.SDM).** The increased likelihood of these events  
5 stems from the following factors:  
6

- 7 ▪ *On balance, changes humans are making to ecosystems are reducing the resilience of*  
8 *the ecological components of the systems (established but incomplete) (C6, S3, S12).*  
9 Genetic and species diversity, as well as spatial patterns of landscapes, environmental  
10 fluctuations, and temporal cycles with which species evolved, generate the resilience  
11 of ecosystems. Functional groups of species contribute to ecosystem processes and  
12 services in similar ways. Diversity among functional groups increases the flux of  
13 ecosystem processes and services (*established but incomplete*). Within functional  
14 groups, species respond differently to environmental fluctuations. This response  
15 diversity derives from variation in the response of species to environmental drivers,  
16 heterogeneity in species distributions, differences in ways that species use seasonal  
17 cycles or disturbance patterns, or other mechanisms. Response diversity enables  
18 ecosystems to adjust in changing environments, altering biotic structure in ways that  
19 maintain processes and services (*high certainty*) (S.SDM). The loss of biodiversity  
20 that is now taking place thus tends to reduce the resilience of ecosystems.  
21
- 22 ▪ *There are growing pressures from various drivers (S7, SG7.5).* Threshold changes in  
23 ecosystems are not uncommon, but they are rarely encountered in the absence of  
24 human-caused pressures on ecosystems. Many of these pressures are now growing.  
25 Increased fish harvests raise the likelihood of fisheries collapses; higher rates of  
26 climate change boost the potential for species extinctions; increased introductions of  
27 nitrogen and phosphorus into the environment make the eutrophication of aquatic  
28 ecosystems more likely; as human populations become more mobile, more and more  
29 species are being introduced into new habitats, and this increases the chance of  
30 harmful pests emerging in those regions.

31 **The growing bushmeat trade poses particularly significant threats associated with**  
32 **nonlinear changes (C8.3, S.SDM, C14).** Growth in the use and trade of bushmeat is  
33 placing increasing pressure on many species, particularly in Africa and Asia. Once this  
34 pressure exceeds levels of sustainable harvest, the populations of the harvested species  
35 are likely to decline extremely rapidly and could be at risk of extinction. Because of the  
36 growing dependence of some populations on bushmeat as a source of protein, however,  
37 the collapse of the supply of these resources could result in sudden and significant harm  
38 to the food supply of these people. Finally, the bushmeat trade involves relatively high  
39 levels of interaction between humans and some relatively closely related wild animals  
40 that are eaten, and this increases the risk of emergence of new and serious pathogens, as  
41 took place in the case of HIV/AIDS. Given the speed and magnitude of international  
42 travel today, new pathogens could spread rapidly around the world.

43 **A potential nonlinear response, currently the subject of intensive scientific research,**  
44 **is the atmospheric capacity to cleanse itself of air pollution (in particular,**  
45 **hydrocarbons and reactive nitrogen compounds) (C.SDM).** This capacity depends on  
46 chemical reactions involving the hydroxyl radical (OH<sup>-</sup>), the atmospheric concentration of  
47 which has declined by about 10% (*medium certainty*) since preindustrial times. An abrupt

1 decrease in the atmospheric self-cleansing capacity would result in a severe air quality  
2 decline in many urban and industrial regions.

3

4 **Once an ecosystem has undergone a nonlinear change, recovery to the original state**  
5 **may take decades or centuries and may sometimes be impossible.** For example, the

6 recovery of overexploited fisheries that have been closed to fishing is quite variable.

7 Although the cod fishery in Newfoundland has been closed for nearly 10 years, there

8 have been few signs of a recovery, and many scientists are not optimistic about its return

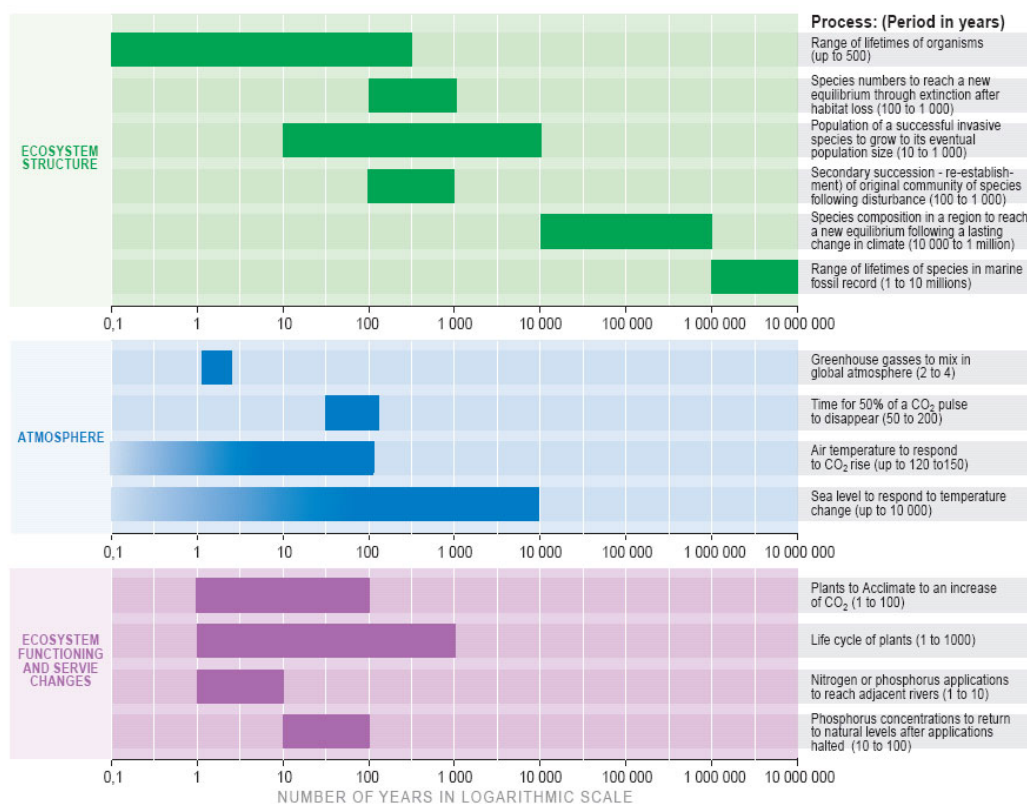

9 in the foreseeable future (C18.3.6). On the other hand, the North Sea Herring fishery

10 collapsed due to overharvesting in the late 1970s, but it recovered after being closed for

11 four years (C18.?? ).

1 **Figure 7.1. Characteristic Time and Space Scales Related to Ecosystems and Their**  
 2 **Services.** Time scale is defined here as the time needed for at least half the process to be  
 3 expressed. The characteristic spatial scale is the spatial area over which the process takes  
 4 place. (Note: For comparison, this table includes references to time and space scales cited  
 5 in the Synthesis Report of the IPCC Third Assessment Report.) [Info in table and figure  
 6 below to be combined. ]  
 7

Process	Spatial Scale (km <sup>2</sup> )	Ref
<b>Atmosphere</b>		
Greenhouse Gasses to mix in global atmosphere	Global	IPCC TAR
50% of a CO <sub>2</sub> pulse to disappear	Global	IPCC TAR
Air temperature to respond to CO <sub>2</sub> rise	Global	IPCC TAR
Sea level to respond to temperature change	Global	IPCC TAR
<b>Ecosystem Structure</b>		
Range size of vertebrate species	0.1 to 100 million	C4 Fig 4.15
Range of species "lifetimes" in marine fossil record		C4.4.2
Species numbers to reach a new equilibrium through extinction after habitat loss	100 to 10,000	S10.1
Species composition in a region to reach a new equilibrium following a lasting change in climate	10 to 10,000	CF7
Secondary Succession (re-establishment of original community of species following disturbance)	1 to 10	CF7
<b>Ecosystem Functioning and Service Changes</b>		
Physiological acclimation of plants to an increase in CO <sub>2</sub>	Local	IPCC TAR
Life cycle of plants	Local	IPCC TAR
Phosphorus concentrations to return to natural levels after applications halted	1 to 10	S7

## 8. What options exist to manage ecosystems sustainably?

It is a major challenge to reverse the degradation of ecosystems while meeting increasing demands for their services. But this challenge can be met. Three of the four MA scenarios show that changes in policy can mitigate many of the negative consequences of growing pressures on ecosystems, although the changes required are large and not currently under way (S.SDM). As noted in Chapter 5, in three of the four MA scenarios at least one of the three categories of provisioning, regulating, and cultural services is in better condition in 2050 than in 2000, although biodiversity loss continues at high rates in all scenarios. The scale of interventions that result in these positive outcomes, however, are very significant. They include major investments in environmentally sound technology, active adaptive management, proactive actions to address environmental problems before their full consequences are experienced, major investments in public goods (such as education and infrastructure), and strong action to reduce economic disparities and eliminate poverty.

**Past actions to slow or reverse the degradation of ecosystems have yielded significant benefits, but these improvements have generally not kept pace with growing pressures and demands.** Although most ecosystem services assessed in the MA are being degraded, the extent of that degradation would have been much greater without responses implemented in past decades. For example, more than 100,000 protected areas (including strictly protected areas such as national parks as well as areas managed for the sustainable use of natural ecosystems, including timber harvest or wildlife harvest) covering about 11.7% of the terrestrial surface have now been established (R5.2.1). These play an important role in the conservation of biodiversity and ecosystem services, although important gaps in the distribution of protected areas remain, particularly in marine and freshwater systems.

Technological advances have also helped to lessen the pressure on ecosystems per unit increase in demand for ecosystem services. For all developing countries, for instance, yields of wheat, rice, and maize rose between 109% and 208% in the past 40 years. Without this increase, far more habitat would have been converted to agriculture during this time.

**An effective set of responses to ensure the sustainable management of ecosystems must address the drivers presented in Chapter 4 and overcome barriers related to (RWG):**

- inappropriate institutional and governance arrangements, including the presence of corruption and weak systems of regulation and accountability;
- market failures and the misalignment of economic incentives;
- social and behavioral factors, including the lack of political and economic power of some groups (such as poor people, women, and indigenous groups) who are particularly dependent on ecosystem services or harmed by their degradation;
- underinvestment in the development and diffusion of technologies that could increase the efficiency of use of ecosystem services and reduce the harmful impacts of various drivers of ecosystem change; and
- insufficient knowledge (as well as the poor use of existing knowledge) concerning ecosystem services and management, policy, technological, behavioral and

1 institutional responses that could enhance benefits from these services while  
2 conserving resources.

3  
4 All these barriers are compounded by weak human and institutional capacity related to  
5 the assessment and management of ecosystem services, underinvestment in the regulation  
6 and management of their use, lack of public awareness, and lack of awareness among  
7 decision-makers of the threats posed by the degradation of ecosystem services and the  
8 opportunities that more sustainable management of ecosystems could provide.

9 **The MA assessed 74 response options for eight ecosystem services along with**  
10 **additional responses related to integrated ecosystem management and one driver—**  
11 **climate change.** (See Appendix B.) Many of these options hold significant promise for  
12 conserving or sustainably enhancing the supply of ecosystem services. Examples of  
13 promising responses that address the barriers just described are presented in the remainder  
14 of this chapter (RWG, R2). The stakeholder groups that would need to take decisions to  
15 implement each response are indicated as follows: G for government, B for business and  
16 industry, and N for nongovernmental organizations and other civil society organizations  
17 such as community-based and indigenous peoples organizations.

## 18 *Institutions and Governance*

19 **Changes in institutional and environmental governance frameworks are often**  
20 **required in order to create the enabling conditions for effective management of**  
21 **ecosystems.** Today's institutions were not designed to take into account the threats  
22 associated with the degradation of ecosystem services, nor were they well designed to  
23 deal with the management of open access resources, a feature of many ecosystem  
24 services. Issues of ownership and access to resources, rights to participation in decision-  
25 making, and regulation of particular types of resource use or discharge of wastes can  
26 strongly influence the sustainability of ecosystem management and are fundamental  
27 determinants of who wins and who loses from changes in ecosystems. Corruption, a  
28 major obstacle to effective management of ecosystems, also stems from weak systems of  
29 regulation and accountability.

30 Promising interventions include:

- 31 ▪ *Integration of ecosystem management goals within other sectors and within broader*  
32 *development planning frameworks* (G). The most important public policy decisions  
33 affecting ecosystems are often made by agencies and in policy arenas other than those  
34 charged with protecting ecosystems. Ecosystem management goals are more likely to  
35 be achieved if they are reflected in decisions in other sectors and in national  
36 development strategies. For example, the Poverty Reduction Strategy Papers prepared  
37 by developing-country governments in collaboration with the World Bank and other  
38 institutions strongly shape national development priorities, but these have not taken  
39 into account the importance of ecosystems to improving the basic human capabilities  
40 of the poorest (R17.ES).
- 41 ▪ *Increased coordination among multilateral environmental agreements and between*  
42 *environmental agreements and other international economic and social institutions*  
43 (G). International agreements are indispensable for addressing ecosystem-related  
44 concerns that span national boundaries, but numerous obstacles weaken their current  
45 effectiveness (R17.2). The limited, focused nature of the goals and mechanisms

1 included in most bilateral and multilateral environmental treaties does not address the  
2 broader issue of ecosystem services and human well-being. Steps are now being taken  
3 to increase coordination among these treaties, and this could help broaden the focus of  
4 the array of instruments. However, coordination is also needed between the  
5 multilateral environmental agreements and the more politically powerful international  
6 legal institutions, such as economic and trade agreements, to ensure that they are not  
7 acting at cross-purposes (R.SDM).

- 8     ▪ *Increased transparency and accountability of government and private-sector*  
9 *performance in decisions that affect ecosystems, including through greater*  
10 *involvement of concerned stakeholders in decision-making* (G, B, N) (RWG; SG9).  
11 Laws, policies, institutions, and markets that have been shaped through public  
12 participation in decision-making are more likely to be effective and perceived as just.  
13 For example, degradation of freshwater and other ecosystem services generally have a  
14 disproportionate impact on those who are, in various ways, excluded from  
15 participation in the decision-making process (R7.2.3). Stakeholder participation also  
16 contributes to the decision-making process because it allows a better understanding of  
17 impacts and vulnerability, the distribution of costs and benefits associated with trade-  
18 offs, and the identification of a broader range of response options that are available in  
19 a specific context. And stakeholder involvement and transparency of decision-making  
20 can increase accountability and reduce corruption.
  
- 21     ▪ *Development of institutions that devolve (or centralize) decision-making to meet*  
22 *management needs while ensuring effective coordination across scales* (G, B, N)  
23 (RWG). Problems of ecosystem management have been exacerbated by both overly  
24 centralized and overly decentralized decision-making. For example, highly centralized  
25 forest management has proved ineffective in many countries, and efforts are now  
26 being made to move responsibility to lower levels of decision-making either within  
27 the natural resources sector or as part of broader decentralization of governmental  
28 responsibilities. At the same time, one of the most intractable problems of ecosystem  
29 management has been the lack of alignment between political boundaries and units  
30 appropriate for the management of ecosystem goods and services. Downstream  
31 communities may not have access to the institutions through which upstream actions  
32 can be influenced; alternatively, downstream communities or countries may be  
33 stronger politically than upstream regions and may dominate control of upstream  
34 areas without addressing upstream needs. A number of countries, however, are now  
35 strengthening regional institutions for the management of transboundary ecosystems  
36 (such as the Danube River, the Mekong River Commission, East African cooperation  
37 on Lake Victoria, and the Amazon Cooperation Treaty Organization).
  
- 38     ▪ *Development of institutions to regulate interactions between markets and ecosystems*  
39 (G) (RWG). The potential of policy and market reforms to improve ecosystem  
40 management are often constrained by weak or absent institutions. For example, the  
41 potential of the Clean Development Mechanism established under the Framework  
42 Convention on Climate Change to provide financial support to developing countries  
43 in return for greenhouse gas reductions, which would realize climate and biodiversity  
44 benefits through payments for carbon sequestration in forests, is constrained by  
45 unclear property rights, concerns over the permanence of reductions, and lack of  
46 mechanisms for resolving conflicts. Moreover, existing regulatory institutions often  
47 do not have ecosystem protection as a clear mandate. For example, independent

1 regulators of privatized water systems and power systems do not necessarily promote  
2 resource use efficiency and renewable supply. There is a continuing importance of the  
3 role of the state to set and enforce rules even in the context of privatization and  
4 market-led growth.

- 5 ▪ *Development of institutional frameworks that promote a shift from highly sectoral*  
6 *resource management approaches to more integrated approaches* (G, B) (R15.ES,  
7 R12.ES, R11.ES). In most countries, separate ministries are in charge of different  
8 aspects of ecosystems (such as ministries of environment, agriculture, water, and  
9 forests) and different drivers of change (such as ministries of energy, transportation,  
10 development, and trade). Each of these ministries has control over different aspects of  
11 ecosystem management. As a result, there is seldom the political will to develop  
12 effective ecosystem management strategies, and competition among the ministries can  
13 often result in policy choices that are detrimental to ecosystems. Integrated responses  
14 intentionally and actively address ecosystem services and human well-being  
15 simultaneously, such as integrated coastal zone management, integrated river basin  
16 management, and national sustainable development strategies. Although the potential  
17 for integrated responses is high, numerous barriers have limited their effectiveness:  
18 they are resource-intensive, but the potential benefits can exceed the costs; they  
19 require multiple instruments for their implementation; and they require new  
20 institutional and governance structures, skills, knowledge, and capacity. Thus far, the  
21 results of implementation of integrated responses have been mixed in terms of  
22 ecological, social, and economic impacts.

### 23 *Economics and Incentives*

24 **Economic and financial interventions provide powerful instruments to regulate the**  
25 **use of ecosystem goods and services** (C5 Box 5.1). Because many ecosystem services  
26 are not traded in markets, markets fail to provide appropriate signals that might otherwise  
27 contribute to the efficient allocation and sustainable use of the services. Even if people  
28 are aware of the services provided by an ecosystem, they are neither compensated for  
29 providing these services nor penalized for reducing them. In addition, the people harmed  
30 by the degradation of ecosystem services are often not the ones who benefit from the  
31 actions leading to their degradation, and so those costs are not factored into management  
32 decisions. A wide range of opportunities exists to influence human behavior to address  
33 this challenge in the form of economic and financial instruments. Some of them establish  
34 markets; others work through the monetary and financial interests of the targeted social  
35 actors; still others affect relative prices.

36 **Market mechanisms can only work if supporting institutions are in place, and thus**  
37 **there is a need to build institutional capacity to enable more widespread use of these**  
38 **mechanisms** (R17). The adoption of economic instruments usually requires a legal  
39 framework, and in many cases the choice of a viable and effective economic intervention  
40 mechanism is determined by the socioeconomic context. For example, resource taxes can  
41 be a powerful instrument to guard against the overexploitation of an ecosystem service,  
42 but an effective tax scheme requires well-established and reliable monitoring and tax  
43 collection systems. Similarly, subsidies can be effective to introduce and implement  
44 certain technologies or management procedures, but they are inappropriate in settings that  
45 lack the transparency and accountability needed to prevent corruption. The establishment  
46 of market mechanisms also often involves explicit decisions about wealth distribution and

1 resource allocation, when, for example, decisions are made to establish private property  
2 rights for resources that were formerly considered common pool resources. For that  
3 reason, the inappropriate use of market mechanisms can further exacerbate problems of  
4 poverty.

5 Promising interventions include:

6 ▪ *Elimination of subsidies that promote excessive use of ecosystem services (and, where*  
7 *possible, transfer of these subsidies to payments for nonmarketed ecosystem services)*  
8 (G) (S7.ES). Subsidies paid to the agricultural sectors of OECD countries between  
9 2001 and 2003 averaged over \$324 billion annually, or one third the global value of  
10 agricultural products in 2000. Many countries outside the OECD also have  
11 inappropriate subsidies. A significant proportion of this total involves production  
12 subsidies that lead to overproduction, reduce the profitability of agriculture in  
13 developing countries, and promote overuse of water, fertilizers, and pesticides. They  
14 also increase land values, adding to landowners' resistance to subsidy reductions. On  
15 the social side, agricultural subsidies make farmers overly dependent on taxpayers for  
16 their livelihood, change wealth distribution and social composition by benefiting large  
17 corporate farms to the detriment of smaller family farms, and contribute to the  
18 dependence of large segments of the developing world on aid. Finally, it is not clear  
19 that these policies achieve one of their primary targets—supporting farmers' income.  
20 Only about a quarter of the total expenses in price supports translate into additional  
21 income for farm households.

22 Similar problems are created by fishery subsidies, which for the OECD countries  
23 were estimated at \$6.2 billion in 2002, or about 20% of the gross value of production  
24 that year (C8.4.1). Subsidies on fisheries, apart from their distributional impacts,  
25 affect the management of resources and their sustainable use by encouraging  
26 overexploitation of the resource, thereby worsening the common property problem  
27 present in fisheries. Although some indirect subsidies, such as payments for the  
28 withdrawal of individual transferable harvest quotas, could have a positive impact on  
29 fisheries management, the majority of subsidies have a negative effect. Inappropriate  
30 subsidies are also common in sectors such as water and forestry.

31 Although removal of production subsidies would produce net benefits, it would not  
32 occur without costs. The farmers and fishers benefiting directly from the subsidies  
33 would suffer the most immediate losses, but there would also be indirect effects on  
34 ecosystems both locally and globally. In some cases it may be possible to transfer  
35 production subsidies to other activities that promote ecosystem stewardship, such as  
36 payment for the provision or enhancement of regulatory or supporting services.  
37 Compensatory mechanisms may be needed for the poor who are adversely affected by  
38 the immediate removal of subsidies (R17.5). Reduced subsidies within the OECD  
39 may lessen pressures on some ecosystems in those countries, but they could lead to  
40 more rapid conversion and intensification of land for agriculture in developing  
41 countries and would thus need to be accompanied by policies to minimize the adverse  
42 impacts on ecosystems there.

43 ▪ *Greater use of economic instruments and market-based approaches in the*  
44 *management of ecosystem services* (G, B, N) (RWG). Economic instruments and

1 market mechanisms with the potential to enhance the management of ecosystem  
2 services include:

- 3 ○ *Taxes or user fees for activities with “external” costs* (trade-offs not accounted for  
4 in the market). These instruments create an incentive that lessens the external  
5 costs and provides revenues that can help protect the damaged ecosystem services.  
6 Examples include taxes on excessive application of nutrients or ecotourism user  
7 fees.
- 8 ○ *Creation of markets, including through cap-and-trade systems.* Ecosystem  
9 services that have been treated as “free” resources, as is often the case for water,  
10 tend to be used wastefully. The establishment of markets for the services can both  
11 increase the incentives for their conservation and increase the economic efficiency  
12 of their allocation if supporting legal and economic institutions are in place.  
13 However, as noted earlier, while markets will increase the efficiency of the use of  
14 the resource, they can have harmful effects on particular groups of users who may  
15 inequitably affected by the change (R17). The combination of regulated emission  
16 caps, coupled with market mechanisms for trading pollution rights, often provides  
17 an efficient means of reducing emissions harmful to ecosystems. For example,  
18 nutrient trading systems may be a low-cost way to reduce water pollution in the  
19 United States (R7.Box 7.3).

20 One of the most rapidly growing markets related to ecosystem services is the  
21 carbon market. (See Figure 8.1.) Approximately 64 million tons of carbon  
22 dioxide equivalent were exchanged through projects from January to May 2004,  
23 nearly as much as during all of 2003 (78 million tons) (C5 Box 5.1). The value of  
24 carbon dioxide trades in 2003 was approximately \$300 million. About one quarter  
25 of the trades (by volume of CO<sub>2</sub> equivalents) involve investment in ecosystem  
26 services (hydropower or biomass). The World Bank has established a fund with a  
27 capital of \$33.3 million (as of January 2005) to invest in afforestation and  
28 reforestation projects that sequester or conserve carbon in forest and  
29 agroecosystems while promoting biodiversity conservation and poverty  
30 alleviation. It is speculated that the value of the global carbon emissions trading  
31 markets could reach \$44 billion in 2010 (and involve trades totaling 4.5 billion  
32 tons of carbon dioxide or equivalent).

- 33 ○ *Payment for ecosystem services.* Mechanisms can be established to enable  
34 individuals, firms, or the public sector to pay resource owners to provide  
35 particular services. For example, in New South Wales, Australia, associations of  
36 farmers purchase salinity credits from the State Forests Agency, which in turn  
37 contracts with upstream landholders to plant trees, which reduce water tables and  
38 store carbon. Similarly, in 1996 Costa Rica established a nationwide system of  
39 conservation payments to induce landowners to provide ecosystem services.  
40 Under this program, the government brokers contracts between international and  
41 domestic “buyers” and local “sellers” of sequestered carbon, biodiversity,  
42 watershed services, and scenic beauty. By 2001, more than 280,000 hectares of  
43 forests had been incorporated into the program at a cost of about \$30 million, with  
44 pending applications covering an additional 800,000 hectares (C5 Box 5.1).

45 Other innovative conservation financing mechanisms include “biodiversity  
46 offsets” (whereby developers pay for conservation activities as compensation for  
47 unavoidable harm that a project causes to biodiversity). An online news site, the  
48 Ecosystem Marketplace, has now been established by a consortium of institutions  
49 to provide information on the development of markets for ecosystem services and  
50 the payments for them.

- 1       ○ *Mechanisms to enable consumer preferences to be expressed through markets.*  
2       Consumer pressure may provide an alternative way to influence producers toward  
3       more sustainable production practices in the absence of effective government  
4       regulation. For example, certification schemes that exist for sustainable fisheries  
5       and forest practices provide people with the opportunity to promote sustainability  
6       through their consumer choices. Within the forest sector, forest certification has  
7       become widespread in many countries and forest conditions; thus far, however,  
8       most certified forests are in temperate regions, managed by large companies that  
9       export to northern retailers (R8).

## 10 ***Social and Behavioral Responses***

11

12 **Social and behavioral responses—including population policy; public education;**  
13 **empowerment of communities, women, and youth; and civil society actions—can be**  
14 **instrumental in responding to ecosystem degradation.** These are generally  
15 interventions that stakeholders initiate and execute through exercising their procedural or  
16 democratic rights in efforts to improve ecosystems and human well-being.

17 Promising interventions include:

- 18       ▪ *Changes in consumption* (G, B, N) (RWG). The choices about what individuals  
19       consume and how much they consume are influenced not just by considerations of  
20       price but also by behavioral factors related to culture, ethics, and values. Behavioral  
21       changes that could reduce demand for threatened ecosystem services can be  
22       encouraged through actions by governments (such as education and public awareness  
23       programs or the promotion of demand-side management), industry (such as improved  
24       product labeling or commitments to use raw materials from sources certified as  
25       sustainable), and civil society (such as public awareness campaigns).
- 26       ▪ *Communication and education* (G, B, N) (RWG, R5). Improved communication and  
27       education are essential to achieve the objectives of the environmental conventions, the  
28       Johannesburg Plan of Implementation, and the sustainable management of natural  
29       resources more generally. Both the public and decision-makers can benefit from  
30       education concerning ecosystems and human well-being, but education more  
31       generally provides tremendous social benefits that can help address many indirect  
32       drivers of ecosystem degradation. Barriers to the effective use of communication and  
33       education include a failure to use research and apply modern theories of learning and  
34       change. While the importance of communication and education is well recognized,  
35       providing the human and financial resources to undertake effective work is a  
36       continuing barrier.
- 37       ▪ *Empowerment of groups particularly dependent on ecosystem services or affected by*  
38       *their degradation, including women, indigenous people, and young people* (G, B, N)  
39       (RWG). Despite women’s knowledge about the environment and the potential they  
40       possess, their participation in decision-making has often been restricted by social and  
41       cultural structures. Young people are key stakeholders in that they will experience the  
42       longer-term consequences of decisions made today concerning ecosystem services.  
43       Indigenous control of traditional homelands is often presented as having  
44       environmental benefits by indigenous peoples and their supporters, although the  
45       justification continues to be based on human and cultural rights.

## 1 *Technological Responses*

2  
3 **Given the growing demands for ecosystem services and other increased pressures on**  
4 **ecosystems, the development and diffusion of technologies designed to increase the**  
5 **efficiency of resource use or reduce the impacts of drivers such as climate change**  
6 **and nutrient loading are essential.** Technological change has been essential for meeting  
7 growing demands for some ecosystem services, and technology holds considerable  
8 promise to help meet future growth in demand. Technologies already exist for reducing  
9 nutrient pollution at reasonable costs, for example, but new policies are needed for these  
10 tools to be applied on a sufficient scale to slow and ultimately reverse the increase in  
11 nutrient loading (recognizing that this global goal must be achieved even while increasing  
12 nutrient applications in relatively poor regions such as sub-Saharan Africa). Many  
13 negative impacts on ecosystems and human well-being have resulted from these  
14 technological changes, however (R17.ES). The cost of “retrofitting” technologies once  
15 their negative consequences become apparent can be extremely high, so careful  
16 assessment is needed prior to the introduction of new technologies.

17  
18 Promising interventions include:

- 19 ▪ *Promotion of technologies that increase crop yields without any harmful impacts*  
20 *related to water, nutrient, and pesticide use* (G, B, N) (R6). Agricultural expansion  
21 will continue to be one of the major drivers of biodiversity loss well into the twenty-  
22 first century. Development, assessment, and diffusion of technologies that could  
23 increase the production of food per unit area sustainably without harmful trade-offs  
24 related to excessive use of water, nutrients, or pesticides would significantly lessen  
25 pressure on other ecosystem services. Without the intensification that has taken place  
26 since 1950, a further 20 million square kilometers of land would have had to be  
27 brought into production to achieve today’s crop production (C.SDM). The challenge  
28 for the future is to similarly reduce the pressure for expansion of agriculture without  
29 simultaneously increasing pressures on ecosystem services due to water use,  
30 excessive nutrient loading, and pesticide use.
- 31 ▪ *Restoration of ecosystem services* (G, B, N) (RWG, R7.4). Ecosystem restoration  
32 activities are now common in many countries and include actions to restore almost all  
33 types of ecosystems, including wetlands, forests, grasslands, estuaries, coral reefs, and  
34 mangroves. Ecosystems similar to the ones that were present before conversion can  
35 often be established and can provide some of the original ecosystem services (such as  
36 pollution filtration in wetlands or timber production from forests). The restored  
37 systems seldom fully replace the original systems, but they still help meet needs for  
38 particular services. Yet the cost of restoration is generally extremely high in relation  
39 to the cost of preventing the degradation of the ecosystem.

## 40 *Knowledge and Cognitive Responses*

41  
42 **Effective management of ecosystems is constrained both by a lack of knowledge and**  
43 **information concerning different aspects of ecosystems and by the failure to use**  
44 **adequately the information that does exist in support of management decisions.**  
45 Although sufficient information exists to take many actions that could help conserve  
46 ecosystems and enhance human well-being, major information gaps exist. In most  
47 regions, for example, relatively little is known about the status and economic value of

1 most ecosystem services, and their depletion is rarely tracked in national economic  
2 accounts. Limited information exists about the likelihood of nonlinear changes in  
3 ecosystems or the location of thresholds where such changes may be encountered. Basic  
4 global data on the extent and trend in different types of ecosystems and land use are  
5 surprisingly scarce. Models used to project future environmental and economic conditions  
6 have limited capability of incorporating ecological “feedbacks” including nonlinear  
7 changes in ecosystems.

8  
9 At the same time, decision-makers do not use all of the relevant information that is  
10 available. This is due in part to institutional failures that prevent existing policy-relevant  
11 scientific information from being made available to decision-makers. But it is also due to  
12 the failure to incorporate other forms of knowledge and information, such as traditional  
13 knowledge and practitioners’ knowledge, that are often of considerable value for  
14 ecosystem management.

15  
16 Promising interventions include:

- 17 ▪ *Incorporate both the market and nonmarket values of ecosystems in resource*  
18 *management decisions (G, B) (RWG). Most resource management decisions are*  
19 *strongly influenced by considerations of the monetary costs and benefits of alternative*  
20 *policy choices. In the case of ecosystem management, however, this often leads to*  
21 *outcomes that are not in the interest of society, since the nonmarketed values of*  
22 *ecosystems may exceed the marketed values. As a result, many existing resource*  
23 *management policies favor sectors such as agriculture, forestry, and fisheries at the*  
24 *expense of the use of these same ecosystems for water supply, recreation, and cultural*  
25 *services that may be of greater economic value. Decisions can be improved if they*  
26 *include the total economic value of alternative management options and involve*  
27 *deliberative mechanisms that bring to bear noneconomic considerations as well.*
  
- 28 ▪ *Use of all relevant forms of knowledge and information in assessments and decision-*  
29 *making, including traditional and practitioners’ knowledge (G, B, N) (RWG, C17-*  
30 *ES). Effective management of ecosystems typically requires “place-based”*  
31 *knowledge—information about the specific characteristics and history of an*  
32 *ecosystem. Formal scientific information is often one source of such information, but*  
33 *traditional knowledge or practitioners’ knowledge held by local resource managers*  
34 *can be of equal or greater value. While that knowledge is used in the decisions taken*  
35 *by those who have it, it is too rarely incorporated into other decision-making*  
36 *processes and is often inappropriately dismissed.*
  
- 37 ▪ *Enhancement of human and institutional capacity for assessing the consequences of*  
38 *ecosystem change for human well-being and acting on such assessments (G, B, N)*  
39 *(RWG). Greater technical capacity is needed for agriculture, forest, and fisheries*  
40 *management. But the capacity that exists for these sectors, as limited as it is in many*  
41 *countries, is still vastly greater than the capacity for effective management of other*  
42 *ecosystem services. Because awareness of the importance of these other services has*  
43 *only recently grown, there is limited experience with assessing ecosystem services*  
44 *fully. Serious limits exist in all countries, but especially in developing countries, in*  
45 *terms of the expertise needed in such areas as monitoring changes in ecosystem*  
46 *services, economic valuation or health assessment of ecosystem changes, and policy*  
47 *analysis related to ecosystem services. Even when such assessment information is*

1 available, however, the traditional highly sectoral nature of decision-making and  
2 resource management makes the implementation of recommendations difficult. This  
3 constraint can also be overcome through increased training of individuals in existing  
4 institutions and through institutional reforms to build capacity for more integrated  
5 responses.

## 6 *Design of Effective Decision-making Processes*

7 **Decisions affecting ecosystems and their services can be improved by changing the**  
8 **processes used to reach those decisions.** The context of decision-making about  
9 ecosystems is changing rapidly. The new challenge to decision-making is to make  
10 effective use of information and tools in this changing context in order to improve the  
11 decisions. At the same time, some old challenges must still be addressed. The decision-  
12 making process and the actors involved influence the intervention chosen. Decision-  
13 making processes vary across jurisdictions, institutions, and cultures. Yet the MA has  
14 identified the following elements of decision-making processes related to ecosystems and  
15 their services that tend to improve the decisions reached and their outcomes for  
16 ecosystems and human well-being (R18ES):

- 17 ○ Use the best available information, including considerations of the value of both  
18 marketed and nonmarketed ecosystem services.
- 19 ○ Ensure transparency and the effective and informed participation of important  
20 stakeholders.
- 21 ○ Recognize that not all values at stake can be quantified, and thus quantification  
22 can provide a false objectivity in decision processes that have significant  
23 subjective elements.
- 24 ○ Strive for efficiency, but not at the expense of effectiveness.
- 25 ○ Consider equity and vulnerability in terms of the distribution of costs and benefits.
- 26 ○ Ensure accountability and provide for regular monitoring and evaluation.
- 27 ○ Consider cumulative and cross-scale effects and, in particular, assess trade-offs  
28 across different ecosystem services.

29  
30 **A wide range of deliberative tools (which facilitate transparency and stakeholder**  
31 **participation), information-gathering tools (which are primarily focused on**  
32 **collecting data and opinions), and planning tools (which are typically used to**  
33 **evaluate potential policy options) can assist decision-making concerning ecosystems**  
34 **and their services (R3 Tables 3.6 to 3.8).** Deliberative tools include neighborhood  
35 forums, citizens' juries, community issues groups, consensus conferences, electronic  
36 democracy, focus groups, issue forums, and ecosystem service user forums. Examples of  
37 information-gathering tools include citizens' research panels, deliberative opinion polls,  
38 environmental impact assessments, participatory rural appraisal, and rapid rural appraisal.  
39 Some common planning tools are consensus participation, cost-benefit analysis,  
40 multicriteria analysis, participatory learning and action, stakeholder decision analysis,  
41 trade-off analysis, and visioning exercises. The use of decision-making methods that  
42 adopt a pluralistic perspective is particularly pertinent, since these techniques do not give  
43 undue weight to any particular viewpoint. These tools can be used at a variety of scales,  
44 including global, sub-global, and local.

45 **A variety of frameworks and methods can be used to make better decisions in the**  
46 **face of uncertainties in data, prediction, context, and scale (R4.5).** Commonly used  
47 methods include cost-benefit or multicriteria analyses, risk assessment, the precautionary

1 principle, and vulnerability analysis. (See Table 8.1.) All these methods have been able  
2 to support optimization exercises, but few of them have much to say about equity. Cost-  
3 benefit analysis can, for example, be modified to weight the interests of some people  
4 more than others. The discount rate can be viewed, in long-term analyses, as a means of  
5 weighing the welfare of future generations; and the precautionary principle can be  
6 expressed in terms of reducing the exposure of certain populations or systems whose  
7 preferential status may be the result of equity considerations. Only multicriteria analysis  
8 was designed primarily to accommodate optimization across multiple objectives with  
9 complex interactions, but this can also be adapted to consider equity and threshold issues  
10 at national and sub-national scales. Finally, the existence and significance of various  
11 thresholds for change can be explored by several tools, but only the precautionary  
12 principle was designed explicitly to address such issues.

13 **Scenarios provide one way to cope with many aspects of uncertainty, but our limited**  
14 **understanding of ecological and human response processes shrouds any individual**  
15 **scenario in its own characteristic uncertainty (R4ES).** Scenarios can be used to  
16 highlight the implications of alternative assumptions about critical uncertainties related to  
17 the behavior of human and ecological systems. In this way, they provide one means to  
18 cope with many aspects of uncertainty in assessing responses. The relevance,  
19 significance, and influence of scenarios ultimately depend on who is involved in their  
20 development (SG9.ES).

21 At the same time, though, there are a number of reasons to be cautious in the use of  
22 scenarios. First, individual scenarios represent conditional projections based on these  
23 specific assumptions. Thus, to the extent that our understanding and representation of the  
24 ecological and human systems represented in the scenarios is limited, specific scenarios  
25 are characterized by their own uncertainty. Second, there is uncertainty in translating the  
26 lessons derived from scenarios developed at one scale—say, global—to the assessment of  
27 responses at other scales—say, sub-national. Third, scenarios often have hidden and hard-  
28 to-articulate assumptions. Fourth, environmental scenarios have tended to more  
29 effectively incorporate state-of-the-art natural science modeling than social science  
30 modeling.

31 **Historically, most responses addressing ecosystem services have concentrated on the**  
32 **short-term benefits from increasing the productivity of provisioning services (RWG).**  
33 Far less emphasis has been placed on managing regulating, cultural, and supporting  
34 ecosystem services; on management goals related to poverty alleviation and equitable  
35 distribution of benefits from ecosystem services; and on the long-term consequences of  
36 ecosystem change on the provision of services. As a result, the current management  
37 regime falls far short of the potential for meeting human needs and conserving  
38 ecosystems.

39 **Effective management of ecosystems requires coordinated responses at multiple**  
40 **scales (SG9; R17.ES).** Responses that are successful at a small scale are often less  
41 successful at higher levels due to constraints in legal frameworks and government  
42 institutions that prevent their success. In addition, there appear to be limits to scaling up,  
43 not only because of these higher-level constraints, but also because interventions at a  
44 local level often address only direct drivers of change rather than indirect or underlying  
45 ones. For example, a local project to improve livelihoods of communities surrounding a  
46 protected area in order to reduce pressure on it, if successful, may increase migration into  
47 buffer zones, thereby adding to pressures. Cross-scale responses may be more effective at

1 addressing the higher-level constraints and leakage problems and simultaneously tackling  
2 regional and national as well as local-level drivers of change. Examples of successful  
3 cross-scale responses include some co-management approaches to natural resource  
4 management in fisheries and forestry and multistakeholder policy processes (R15-ES).

5 **Failure to acknowledge that stakeholders at different scales perceive different values**  
6 **in various ecosystem services can lead to unworkable and inequitable policies or**  
7 **programs at all scales** (SGWG). Ecosystem services that are of considerable importance  
8 at global scales, such as carbon sequestration or waste regulation, are not necessarily seen  
9 to be of value locally. Similarly, services of local importance, such as the cultural benefits  
10 of ecosystems, the availability of manure for fuel and fertilizer, or the presence of non-  
11 timber forest products, are often not seen as important globally. Responses designed to  
12 achieve goals related to global or regional concerns are likely to fail unless they take into  
13 account the different values and concerns motivating local communities.

14 **Active adaptive management can be a particularly valuable tool for reducing**  
15 **uncertainty about ecosystem management decisions** (R17.4.5). The term “active”  
16 adaptive management is used here to emphasize the key characteristic of the original  
17 concept (which is frequently and inappropriately used to mean “learning by doing”): the  
18 design of management programs to test hypotheses about how components of an  
19 ecosystem function and interact and to thereby reduce uncertainty about the system more  
20 rapidly than would otherwise occur. Under an adaptive management approach, for  
21 example, a fisheries manager might intentionally set harvest levels either lower or higher  
22 than the “best estimate” in order to gain information more rapidly about the shape of the  
23 yield curve for the fishery. Given the high levels of uncertainty surrounding coupled  
24 socioecological systems, the use of active adaptive management is often warranted.

25  
26

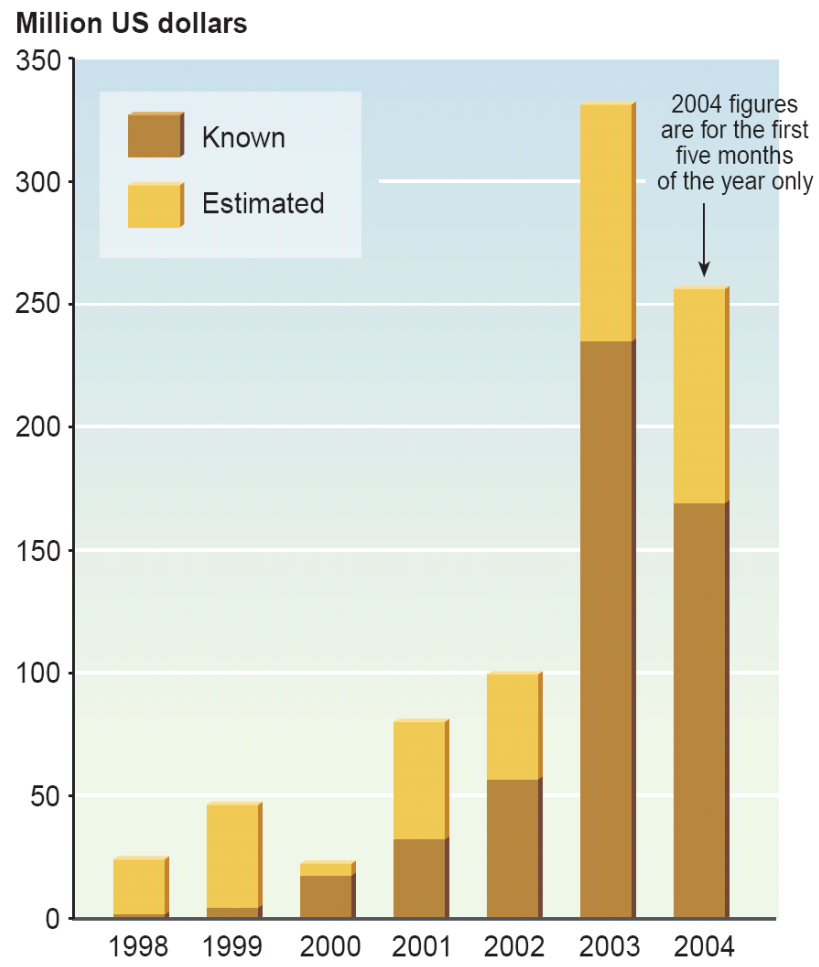

1 **Table 8.1. Applicability of Decision Support Methods and Frameworks** (R4 Table  
 2 4.1) Key: **++** = direct application of the method by design  
 3 **+** = possible application with modification or (in the case of uncertainty) the  
 4 method has already been modified to handle uncertainty  
 5 **-** = weak but not impossible applicability with significant effort

Method	Optimization	Equity	Thresholds	Uncertainty	Scale of Application		
					Micro	National	Regional and Global
Cost Benefit Analysis	+	+	-	+			
Risk Assessment	+	+	++	++			
Multi-criteria Analysis	++	+	+	+			
Precautionary Principle*	+	+	++	++			
Vulnerability Analysis	+	+	++	+			

6

7 \* The precautionary principle is not strictly analogous to the other analytical and assessment methods but  
 8 still can be considered a method for decision support. The precautionary principle prescribes how to bring  
 9 scientific uncertainty into the decision-making process by explicitly formalizing precaution and bringing it to  
 10 the forefront of the deliberations. It posits that significant actions (ranging from doing nothing to banning a  
 11 potentially harmful substance or activity, for instance) may be justified when the degree of possible harm is  
 12 large and irreversible.

## 9. What are the most important uncertainties hindering decision-making concerning ecosystems?

The MA was unable to provide adequate scientific information to answer a number of important policy questions related to ecosystem services and human well-being. In some cases, the scientific information may well exist already but the process used and time frame available prevented either access to the needed information or its assessment. But in many cases it is clear that either the data needed to answer the questions were unavailable or the knowledge of the ecological or social system was inadequate. We identify the following *key uncertainties* that, if reduced, could significantly enhance the ability of a process like the MA to answer policy-relevant questions posed by decision-makers (CWG, SWG, RWG, SGWG) .

### *Conditions and Trends*

- There are major gaps in global and national monitoring systems that result in the absence of well-documented, comparable, time-series information for many ecosystem features and that pose significant barriers in assessing conditions and trends in ecosystem services. Moreover, in a number of cases, including hydrological systems, the condition of the monitoring systems that do exist is declining.
  - Although remote sensing information is now regularly being gathered that could enable rigorous global monitoring of habitat change, financial resources are not available to process this information, and thus accurate measurements of land cover change are only available on a case study basis.
  - Information on land degradation in drylands is extremely poor. Major shortcomings in the currently available assessments point to the need for a systematic global monitoring program, leading to the development of a scientifically credible, consistent baseline of the state of land degradation and desertification.
  - There is little replicable data on global forest extent that can be tracked over time
  - There is no reasonably accurate global map of wetlands.
- There are major gaps in information on nonmarketed ecosystem services, particularly regulating, cultural, and supporting services.
- There is no complete inventory of species and limited information on the actual distributions of many important plant and animal species.
- Research in the following areas could significantly improve information available for decision-makers:
  - the nature of interactions among drivers in particular regions and across scales;
  - the responses of ecosystems to changes in the availability of important nutrients and carbon dioxide;
  - nonlinear changes in ecosystems, predictability of thresholds, and structural and dynamic characteristics of systems that lead to threshold and irreversible changes; and
  - quantification and prediction of the relationships between biodiversity changes and changes in ecosystem services for particular places and times.

- 1   ▪ There is limited information on the economic consequences of changes in ecosystem  
2   services at any scale and, more generally, limited information on the details of  
3   linkages between human well-being and the provision of ecosystem services, except  
4   in the case of food and water.
- 5   ▪ There is a general lack of models for the relationship between ecosystem services and  
6   human well-being.

### 7   *Scenarios*

- 8   ▪ There is a lack of analytical and methodological approaches to explicitly nest or link  
9   scenarios developed at different geographic scales. This innovation would provide  
10   decision-makers with information that directly links local, national, regional, and  
11   global futures of ecosystem services in considerable detail.
- 12   ▪ There is limited modeling capability related to effects of changes in ecosystems on  
13   flows of ecosystem services and effects of changes in ecosystem services on changes  
14   in human well-being. Quantitative models linking ecosystem change to many  
15   ecosystem services are also needed.
- 16   ▪ Significant advances are needed in models that link ecological and social processes,  
17   and models do not yet exist for many cultural and supporting ecosystem services.
- 18   ▪ There is limited capability of incorporating adaptive responses and changes in human  
19   attitudes and behaviors in models and of incorporating critical feedbacks into  
20   quantitative models. As food supply changes, for example, so will patterns of land  
21   use, which will then feed back on ecosystem services and climate alteration and future  
22   food supplies.
- 23   ▪ There is a lack of theories and models that anticipate thresholds that, once passed,  
24   yield fundamental system changes or even system collapse.
- 25   ▪ There is limited capability of communicating to nonspecialists the complexity  
26   associated with holistic models and scenarios involving ecosystem services, in  
27   particular in relation to the abundance of nonlinearities, feedbacks, and time lags in  
28   most global ecosystems.

### 29   *Response Options*

- 30   ▪ There is limited information on the marginal costs and benefits of alternative policy  
31   options in terms of total economic value (including nonmarketed ecosystem services).
- 32   ▪ Substantial uncertainty exists with respect to who benefits from watershed services  
33   and how changes in particular watersheds influence those services; information in  
34   both of these areas is needed in order to determine whether markets for watershed  
35   services can be a fruitful response option.
- 36   ▪ There has been little social science analysis of the effectiveness of responses on  
37   biodiversity conservation.

- 1   ▪ There is considerable uncertainty with regards to the importance people in different  
2   cultures place on cultural services, how this changes over time, and how it influences  
3   the net costs and benefits of trade-offs and decisions.

4

5

## 1 **Appendix A. Ecosystem Service Reports**

2 This Appendix presents some of the main findings from the Condition and Trends  
3 Working Group and the Scenarios Working Group for a selected set of ecosystem  
4 services addressed in the Millennium Ecosystem Assessment.

2 People obtain food from highly managed systems such as crops, livestock, and aquaculture and  
3 also from wild sources, including freshwater and marine capture fisheries and the harvesting of  
4 wild plants and animals (bushmeat, for example).

### 5 **Condition and Trends**

- 6   ▪ Food production more than doubled (an increase of over 160%) from 1961 to 2003. (C8.1)  
7    (See Appendix Figure A.1.) Over this period, production of cereals—the major energy  
8    component of human diets—has increased almost two and a half times, beef and sheep  
9    production increased by 40%, pork production by nearly 60%, and poultry production  
10   doubled. (C8.ES)
- 11   ▪ Over the past 40 years, globally, intensification of cultivated systems has been the primary  
12    source (almost 80%) of increased output. But some countries, predominantly found in Sub-  
13    Saharan Africa, have had persistently low levels of productivity, and continue to rely on  
14    expansion of cultivated area. For all developing countries over the period 1961–99, expansion  
15    of harvested land contributed only 29% to growth in crop production versus the contribution  
16    of increases in yields, which amounted to 71%; in sub-Saharan Africa, however, yield  
17    increases accounted for only 34% of growth in production. (C26.ES, C26.1.1)
- 18   ▪ Both total and per capita fish consumption have grown over the past four decades. Total fish  
19    consumption has declined somewhat in industrial countries, while it has nearly doubled in the  
20    developing world since 1973 (C8.ES).
- 21   ▪ Demand for fish has risen more rapidly than production, leading to increases in the real prices  
22    of most fresh and frozen fish products (C8.ES).
- 23   ▪ Freshwater aquaculture is the fastest-growing food production sector. Worldwide, it has  
24    increased at an average compounded rate of 9.2% per year since 1970, compared with only  
25    1.4% for capture fisheries and 2.8% for terrestrial farmed meat production systems (C26.3.1).  
26    Aquaculture systems now account for roughly 30% of total fish production (C8.ES).
- 27   ▪ The level of global output of cereals has stagnated since 1996, so grain stocks have been in  
28    decline. Although there is concern about these trends, they may reflect only a normal cycle of  
29    market adjustment (C8.2.2).
- 30   ▪ Though there has been some cereal price recovery since 2001, prices are still some 30–40%  
31    lower than their peak in the mid-1990s. (C8.2.2.1)
- 32   ▪ Current patterns of use of capture fisheries are unsustainable. Humans increased the capture  
33    of marine fish up until the 1980s by harvesting an ever-growing fraction of the available  
34    resource. Marine fish landings are now declining as a result of the overexploitation of this  
35    resource (C18.ES). Inland water fisheries, which are particularly important in providing  
36    high-quality diets for poor people, have also declined due to habitat modification, overfishing,  
37    and water withdrawals (C8.ES).
- 38   ▪ While traditional aquaculture is generally sustainable, an increasing share of aquaculture uses  
39    carnivorous species, and this puts increased pressure on other fisheries to provide fishmeal as  
40    feed and also exacerbates waste problems. Shrimp farming often results in severe damage to  
41    mangrove ecosystems, although some countries have taken steps to reduce these harmful  
42    impacts.

1 **Scenarios**

- 2     ▪ All four MA scenarios project increased total and per capita global food production by 2050  
3     (S9). On a per capita basis, however, basic staple production stagnates or declines in the  
4     Middle East and North Africa and increases very little in sub-Saharan Africa for all four  
5     scenarios. Production shortfalls are expected to be covered through increased food imports in  
6     these regions. Agricultural land area continues to increase in developing countries under the  
7     MA scenarios, but declines in industrial countries. (See Appendix Figure A.2.)
- 8     ▪ Global demand for food crops (measured in tons) is projected to grow by 70–85% between  
9     2000 and 2050 (S9.4.1).
- 10    ▪ Demand for both freshwater and marine fish will expand because of increasing human  
11    population and changing food preferences, and the result will be an increasing risk of a major  
12    and long-lasting decline of regional marine fisheries (*medium to high certainty*) (S9.ES).

# 1 Water

## Provisioning and Supporting Service

2 Water is both a provisioning service, since ecosystems are the source of water used by people, and  
3 a supporting service, since water is required for life on Earth and thus supports all other  
4 ecosystem processes. Forest and mountain ecosystems are associated with the largest amounts of  
5 fresh water—57% and 28% of the total runoff, respectively. These systems each provide  
6 renewable water supplies to at least 4 billion people, or two thirds of the global population.  
7 Cultivated and urban systems generate only 16% and 0.2%, respectively, of global runoff, but due  
8 to their close proximity to humans they serve from 4.5–5 billion people. Such proximity is  
9 associated with nutrient and industrial water pollution (C7.ES).

### 10 Condition and Trends

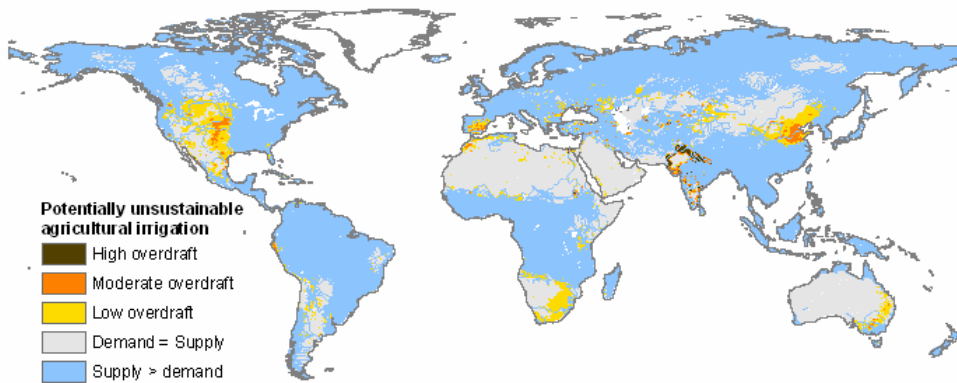

- 11 ▪ Recent changes to ecosystems have not significantly reduced the net amount of renewable  
12 freshwater runoff on Earth, but the fraction of that runoff used by humans has grown  
13 dramatically. Global freshwater use expanded at a mean rate of 20% per decade between  
14 1960 and 2000, doubling over this time period (C7.ES).
- 15 ▪ Contemporary water withdrawal is approximately 10% of global continental runoff, although  
16 this amounts to between 40% and 50% of the continental runoff to which the majority of the  
17 global population has access during the year (C7.ES., (C7.2.3).
- 18 ▪ Inorganic nitrogen pollution of inland waterways has increased more than twofold globally  
19 since 1960 and more than tenfold for many industrialized parts of the world (C7.ES).
- 20 ▪ Current patterns of human use of water are unsustainable. From 5% to possibly 25% of  
21 global freshwater use exceeds long-term accessible supplies and is met through engineered  
22 water transfers or the overdraft of groundwater supplies (*low to medium certainty*). More  
23 than 1 billion people live in areas without appreciable supplies of renewable fresh water and  
24 meet their water needs in this way (C7.ES). In North Africa and the Middle East,  
25 unsustainable use represents about a third of all water use (*low certainty*) (C7.ES).
- 26 ▪ Globally, 15–35% of irrigation withdrawals are estimated to be unsustainable (*low to medium*  
27 *certainty*) (C7.2.2). (See Appendix Figure A.3.)

### 28 Scenarios

- 29 ▪ Use of water is expected to grow by approximately 10% between 2000 and 2010, compared  
30 with rates of 20% per decade over the past 40 years (C7.ES).
- 31 ▪ Water withdrawals began to decline in many parts of the OECD at the end of the twentieth  
32 century, and with *medium certainty* will continue to decline throughout OECD during the  
33 twenty-first century because of saturation of per capita demands, efficiency improvements,  
34 and stabilizing populations (S9.ES).
- 35 ▪ Water withdrawals are expected to increase greatly outside the OECD as a result of economic  
36 development and population growth. The extent of these increases is very scenario-dependent.  
37 In sub-Saharan Africa, domestic water use greatly increases and this implies (*low to medium*  
38 *certainty*) an increased access to fresh water. However, the technical and economic feasibility  
39 of increasing domestic water withdrawals is very uncertain (S9.ES).
- 40 ▪ Across all the MA scenarios, global water withdrawals increase between 30% and 85%  
41 between 2000 and 2050. (S9 Fig 9.35) (See Appendix Figure A.4.)

- 1   ▪ Global water availability increases under all MA scenarios. By 2050, global water  
2    availability increases by 5–7% (depending on the scenario), with Latin America having the  
3    smallest increase (around 2%, depending on the scenario), and the Former Soviet Union the  
4    largest (16–22%) (S9.4.5). Increasing precipitation tends to increase runoff, while warmer  
5    temperatures intensify evaporation and transpiration, which tends to decrease runoff.

1 **Appendix Figure A.3. Unsustainable Water Withdrawals for Irrigation.** (C7 Fig  
 2 7.3) Globally, roughly 15–35% of irrigation withdrawals are estimated to be  
 3 unsustainable (*low to medium certainty*) (C7.2.2). The map indicates where there is  
 4 insufficient fresh water to fully satisfy irrigated crop demands. The imbalance in long-  
 5 term water budgets necessitates diversion of surface water or the tapping of groundwater  
 6 resources. The areas shown with moderate-to-high levels of unsustainable use occur over  
 7 each continent and are known to be areas of aquifer mining or major water transfer  
 8 schemes.

9  
 10 **Key:** *High overdraft*, > 1km<sup>3</sup> yr<sup>-1</sup>; *Moderate*, 0.1 to 1 km<sup>3</sup> yr<sup>-1</sup>; *Low*, 0 to 0.1 km<sup>3</sup> yr<sup>-1</sup>. All estimates made on  
 11 ca. 50 km resolution. Though difficult to generalize, the imbalances translate into water table drawdowns  
 12 >1.6 m yr<sup>-1</sup> or more for the *high overdraft* case and <0.1 m yr<sup>-1</sup> for *low*, assuming water deficits are met by  
 13 pumping unconfined aquifers with typical dewatering potentials (specific yield = 0.2).

14

## Timber, Fiber, Fuel

## Provisioning Services

Timber is harvested from forests and plantations and used for a variety of building, manufacturing, fuel, and other needs. Forests (providing fuelwood and charcoal), agricultural crops, and manure all serve as sources of biomass energy. A wide variety of crops and livestock are used for fiber production. Cotton, flax, hemp, and jute are generally produced from agricultural systems, while sisal is produced from the leaves of Agave cactus. Silk is produced by silkworms fed the leaves of the mulberry tree, grown in an orchard-like culture, and wool is produced by sheep, goats, alpaca, and other animals.

### Condition and Trends

- Global timber harvests increased by 60% since 1960, and wood pulp production increased slightly less than threefold over this same time (C9.ES C9 Table 9.5). Rates of growth in harvests have slowed in recent years.
- Fuelwood is the primary source of energy for heating and cooking for some 2.6 billion people, and 55% of global wood consumption is for fuelwood (C9.ES). Although they account for less than 7% of world energy use, fuelwood and charcoal provide 40% of energy use in Africa and 10% in Latin America (C9.4).
- Global consumption of fuelwood appears to have peaked in the 1990s and is now believed to be slowly declining as a result of switching to alternate fuels and, to a lesser degree, more-efficient biomass energy technologies. In contrast, global consumption of charcoal appears to have doubled between 1975 and 2000, largely as a result of continuing population shifts toward urban areas (C9.4.1).
- Localized fuelwood shortages in Africa impose burdens on people who depend on fuelwood for home heating and cooking (SG3.4). The impact on people may be high prices in urban areas or lengthy and arduous travel to collect wood in rural areas.
- Among agricultural fibers, global cotton production has doubled and silk production has tripled since 1961 (C9.ES). Despite this doubling of production, the land area on which cotton is harvested has stayed virtually the same. Production of flax, wool, hemp, jute, and sisal has declined. For example, competition from synthetic fabrics has contributed to a reduction in the demand for wool in recent decades; wool production declined 16% between 1980 and 2000 (C9.5.3).

### Scenarios

- Plantations are likely to provide an increasing proportion of timber products in the future (C9.ES). In 2000, plantations were 5% of the global forest cover, but they provided some 35% of harvested roundwood, an amount anticipated to increase to 44% by 2020. The most rapid expansion will occur in the mid-latitudes, where yields are higher and production costs lower.
- Under the MA scenarios, forest area increases in industrialized regions and decreases in developing ones between 1970 and 2050. In one scenario (*Order from Strength*), the rate of forest loss increases from the historic rate (of about 0.4% annually between 1970 and 2000) to 0.6%. In the other scenarios, the rate of loss continues at the historic rate (*Global Orchestration* and *Adapting Mosaic*) or slightly below (*TechnoGarden*). (See Figure Appendix A.5.)

# 1 Biochemicals and Genetic Resources Provisioning Services

2 A wide variety of species—microbial, plant, and animal—and their genes contribute to  
 3 commercial products in such industries as pharmaceuticals, botanical medicines, crop protection,  
 4 cosmetics, horticulture, agricultural seeds, environmental monitoring and a variety of  
 5 manufacturing and construction sectors.

## 6 Condition and Trends

- 7
  - Biodiversity is in increasing demand as a source of commercial material. An overview of the  
 8 industries involved, trends in the use of biodiversity, and the types of social and commercial  
 9 benefits is provided in Appendix Table A.1. Appendix Table A.2 is a partial list compounds  
 10 approved for marketing within the pharmaceutical industry in the 1990s.

## 11 Scenarios

- 12
  - Market trends vary widely according to the industry and country involved, but many  
 13 bioprospecting activities and revenues are expected to increase over the next decades. Several  
 14 major new industries, such as bioremediation and biomimetics are well established and appear  
 15 set to increase, while others have a less certain future. The current economic climate suggests  
 16 that pharmaceutical bioprospecting will increase, especially as new methods that use  
 17 evolutionary and ecological knowledge enhance productivity (C10.ES).

18 **Appendix Table A.1. A summary of status and trends in major bioprospecting**  
 19 **industries** (C10 Table 10.8). (+++ = \$billions, ++ = \$millions, + profitable but  
 20 amounts vary; P= plants, A = animals, M= microorganisms)

Porfimer sodium		Quadra Logic
Sorbuzoxane		Zeuyaku Kogyo
Zinostatin		Yamamouchi

Ecosystems, both natural and managed, exert a strong influence on climate and air quality as sources and sinks of pollutants, reactive gases, greenhouse gases, and aerosols and due to physical properties that affect heat fluxes and water fluxes (precipitation). Ecosystems can affect climate in the following ways: warming (as sources of greenhouse gases, for instance, or forests with lower albedo than bare snow); cooling (as sinks of greenhouse gas, sources of some aerosol that reflect solar radiation, and evapotranspiration, for example); and water redistribution/recycling and regional rainfall patterns (through evapotranspiration, for instance, or cloud condensation nuclei).

### Condition and Trends

Changes in ecosystems have made a large contribution to historical changes in radiative forcing from 1750 to the present mainly due to deforestation, fertilizer use, and agricultural practices (C13.ES). (See Figure Appendix A.6.) Ecosystem changes account for about 10–30% of the radiative forcing of CO<sub>2</sub> since 1750 and a large proportion of the radiative forcing due to CH<sub>4</sub> and N<sub>2</sub>O. Ecosystems are currently a net sink for CO<sub>2</sub> and tropospheric ozone, while they remain a net source of CH<sub>4</sub> and N<sub>2</sub>O. Future management of ecosystems has the potential to modify concentrations of a number of greenhouse gases, although this potential is likely to be small in comparison to IPCC scenarios of fossil fuel emissions over the next century (*high certainty*). Ecosystems influence the main anthropogenic greenhouse gases as follows:

- Carbon dioxide: About 40% of the historical emissions (over the last two centuries), and about 20% of current CO<sub>2</sub> emissions (in the 1990s), originated from changes in land use and land management, primarily deforestation. Terrestrial ecosystems were a sink for about a third of cumulative historical emissions and a third of total emissions in the 1990s (energy plus land use). The sink may be explained partially by afforestation, reforestation, and forest management in North America, Europe, China, and other regions and partially by the fertilizing effects of N deposition and increasing atmospheric CO<sub>2</sub>. Terrestrial ecosystems were on average a net source of CO<sub>2</sub> during the nineteenth and early twentieth centuries and became a net sink sometime around the middle of the last century (*high certainty*). The net impact of ocean biology changes on global CO<sub>2</sub> fluxes is unknown.
  - Methane: Natural processes in wetland ecosystems account for about 25–30% of current methane emissions, and about 30% of emissions are due to agriculture (ruminant animals and rice paddies).
  - Nitrous oxide: Ecosystem sources account for about 90% of current N<sub>2</sub>O emissions, with 35% of emissions from agricultural systems, primarily driven by fertilizer use.
  - Tropospheric ozone: Dry deposition in ecosystems accounts for about half the tropospheric ozone sink. Several gases emitted by ecosystems, primarily due to biomass burning, act as precursors for tropospheric ozone formation (NO<sub>x</sub>, volatile organic compounds, CO, CH<sub>4</sub>). The net global effect of ecosystems is as a sink for tropospheric O<sub>3</sub>.
- During much of the past century, most cropping systems have undergone a steady net loss of soil organic matter. However, with the steady increase in crop yields, which increases crop biomass and the amount of residue returned to the soil, and with the adoption of conservation tillage and no-till cropping systems, net carbon sequestration is estimated to occur in the maize-soybean systems of North America and in some continuous irrigated lowland rice systems. Agriculture accounts for 44% of anthropogenic methane emissions and about 70%

1 of anthropogenic nitrous oxide gases, mainly from the conversion of new land to agriculture  
2 and nitrogen fertilizer use (C26.2.6).

3 ■ Terrestrial and marine plants fix atmospheric CO<sub>2</sub> and return it via respiration. In the ocean,  
4 some of the carbon sinks in the form of dead organisms, particles, and dissolved organic  
5 carbon, a small amount of which remains in sediments; the rest is respired at depth and  
6 eventually recirculated to the surface (the “biological pump”). The biological pump acts as a  
7 net sink for CO<sub>2</sub> by increasing its concentration at depth, where it is isolated from the  
8 atmosphere for decades to centuries, causing the concentration of CO<sub>2</sub> in the atmosphere to be  
9 about 200 parts per million lower than it would be in the absence of life (C13.2.1). On the  
10 land large amounts of carbon fixed by plants are stored in soil organic matter.

11 ■ Land cover changes since 1750 have increased the reflectivity to solar radiation (albedo) of  
12 the land surface (*medium certainty*), partially offsetting the warming effect of associated CO<sub>2</sub>  
13 emissions (C13.ES). Deforestation and desertification in the tropics and sub-tropics leads to a  
14 reduction in regional rainfall (*high certainty*). Biophysical effects need to be accounted for in  
15 the assessment of options for climate change mitigation. For example, the warming effect of  
16 reforestation in seasonally snow-covered regions due to albedo decrease is likely to exceed  
17 the cooling effect of additional carbon storage in biomass. Biophysical effects of ecosystem  
18 changes on regional climate patterns depend on geographical location and season. With *high*  
19 *certainty*:

20 • Deforestation in seasonally snow-covered regions leads to regional cooling of the land  
21 surface during the snow season due to increase in surface albedo, and it leads to warming  
22 during the summer due to reduction in evapotranspiration.

23 • Large-scale tropical deforestation (hundreds of square kilometers) reduces regional  
24 rainfall, primarily due to decreased evapotranspiration.

25 • Desertification in the tropics and sub-tropics leads to decrease in regional precipitation  
26 due to reduced evapotranspiration and increased surface albedo.

## 27 Scenarios

28 ■ The future contribution of terrestrial ecosystems to the regulation of climate is uncertain.  
29 Currently, the biosphere is a net sink of carbon, absorbing about 1–2 gigatons of carbon per  
30 year, or approx. 20% of fossil fuel emissions. It is very likely that the future of this service  
31 will be greatly affected by expected land use change. In addition, a higher atmospheric CO<sub>2</sub>  
32 concentration is expected to enhance net productivity, but this does not necessarily lead to an  
33 increase in the carbon sink. The limited understanding of soil respiration processes generates  
34 uncertainty about the future of the carbon sink. There is *medium certainty* that climate change  
35 will increase terrestrial fluxes of CO<sub>2</sub> and CH<sub>4</sub> in some regions (such as in Arctic  
36 tundras).(S9.ES)

1 **Appendix Figure A.6. Contribution of Ecosystems to Historical Radiative Forcing**  
 2 **and Current Greenhouse Gas Emissions (C13 Fig 13.3).** Figure (A) is the radiative  
 3 forcing caused by changes in atmospheric composition, alteration in land surface  
 4 reflectance (albedo), and variation in the output of the sun for the year 2000 relative to  
 5 conditions in 1750. The height of the bar represents a best estimate, and the  
 6 accompanying vertical line a likely range of values. Factors with a significant ecosystem  
 7 influence are separated from those without one. The indirect effect of aerosols shown is  
 8 their effect on cloud droplet size and number, not cloud lifetime.

9 Figure (B) is the relative contribution of ecosystems to sources, sinks, and net changes in  
 10 three main greenhouse gases. These can be compared with each other by conversion into  
 11 CO<sub>2</sub>-equivalent values, based on the global warming potential (radiative impact times  
 12 atmospheric lifetime) of the different gases. For CH<sub>4</sub> and N<sub>2</sub>O, a 100-year time scale was  
 13 assumed; a short time scale would increase the relative value compared with CO<sub>2</sub> and a  
 14 longer time scale would reduce it. Ecosystems are also a net sink for tropospheric ozone,  
 15 but it is difficult to calculate emissions in CO<sub>2</sub>-equivalent values.  
 16

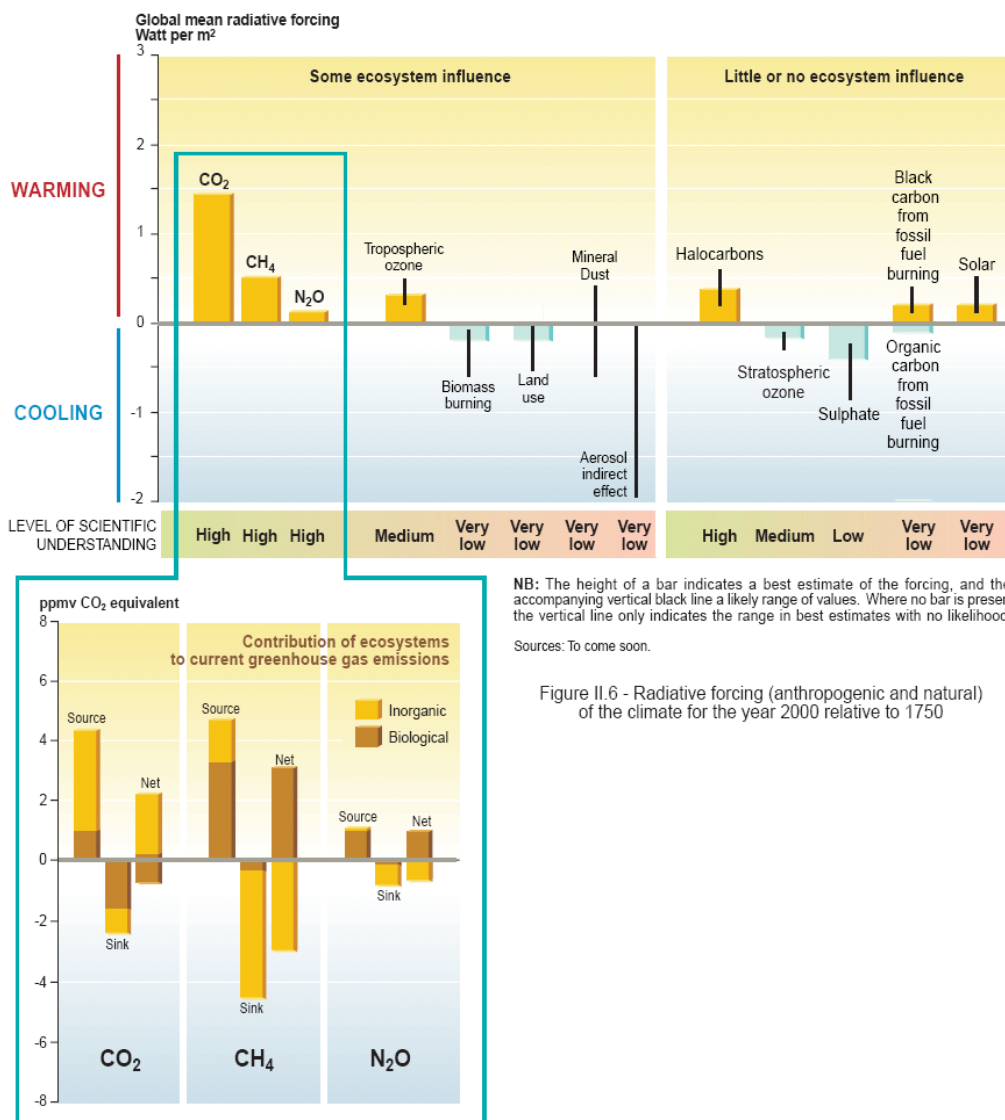

Figure II.6 - Radiative forcing (anthropogenic and natural) of the climate for the year 2000 relative to 1750

# 1 Disease Regulation

## Regulating Service

2 The availability of many ecosystem services, such as food, water, and fuel, can profoundly  
3 influence human health (R16). Here, we consider a much narrower service provided by  
4 ecosystems related to human health: the role of ecosystems in regulating infectious disease.  
5 Ecosystem changes have played an important role in the emergence or resurgence of infectious  
6 diseases. (See Appendix Table A.3.) Ecosystem modifications associated with developments  
7 such as dam building and the expansion of agricultural irrigation, for example, have sometimes  
8 increased the local incidence of infectious diseases such as malaria, schistosomiasis, and  
9 arbovirus infections, especially in the tropics. Other modifications to ecosystems have served to  
10 reduce the incidence of infectious disease.

### 11 Condition and Trends

- 12 ▪ Infectious diseases still account for close to one quarter of the global burden of disease. Major  
13 tropical diseases, particularly malaria, meningitis, leishmaniasis, dengue, Japanese  
14 encephalitis, African trypanosomiasis, Chagas disease, schistosomiasis, filariasis, and  
15 diarrheal diseases still infect millions of people throughout the world (*very certain*) (C14.ES).
  
- 16 ▪ The following diseases are ranked as high priority for their large global burden of disease, in  
17 combination with their high sensitivity to ecological change: malaria across most ecological  
18 systems; schistosomiasis, lymphatic filariasis, and Japanese encephalitis in cultivated and  
19 inland water systems in the tropics; dengue fever in tropical urban centers; leishmaniasis and  
20 Chagas disease in forest and dryland systems; meningitis in the Sahel; cholera in coastal,  
21 freshwater, and urban systems; and West Nile virus and Lyme disease in urban and suburban  
22 systems of Europe and North America (*high certainty*) (C14.ES).
  
- 23 ▪ Various changes to ecosystems can affect disease incidence through a variety of mechanisms.  
24 Disease/ecosystem relationships that best exemplify these biological mechanisms include the  
25 following examples (C14.ES):
  - 26 ▪ Dams and irrigation canals provide ideal habitat for snails that serve as the intermediate  
27 reservoir host species for schistosomiasis; irrigated rice fields increase in the extent of  
28 mosquito-breeding surface, increasing the chance of transmission of mosquito-borne  
29 malaria, lymphatic filariasis, Japanese encephalitis, and Rift Valley fever.
  
  - 30 ▪ Deforestation has increased the risk of malaria in Africa and South America by increasing  
31 habitat suitable for malaria-transmitting mosquitoes.
  
  - 32 ▪ Natural systems with preserved structure and characteristics generally resist the  
33 introduction of invasive human and animal pathogens brought by human migration and  
34 settlement. This seems to be the case of cholera, kala-azar, and schistosomiasis, which did  
35 not become established in the Amazonian forest ecosystem (*medium certainty*).
  
  - 36 ▪ Uncontrolled urbanization in the forest ecosystem has been associated with mosquito-  
37 borne viruses (arboviruses) in the Amazon and with lymphatic filariasis in Africa.  
38 Tropical urban areas with poor water supply systems and lack of shelter promote  
39 transmission of dengue fever.
  
  - 40 ▪ There is evidence that habitat fragmentation, with subsequent biodiversity loss, increases  
41 the prevalence in ticks of the bacteria that causes Lyme disease in North America  
42 (*medium certainty*).

- 1       ▪ Zoonotic pathogens (defined by their natural life cycle in animals) are a significant cause  
2 of both historical (such as HIV and tuberculosis) and newly emerging infectious diseases  
3 affecting humans (such as SARS, West Nile virus, and Hendra virus). In addition,  
4 zoonotic pathogens can cause high case-fatality rates and are difficult to vaccinate against,  
5 since the primary reservoir hosts are nonhumans.
- 6       ▪ Intensive livestock agriculture that uses subtherapeutic doses of antibiotics has led to the  
7 emergence of antibiotic-resistant strains of *Salmonella*, *Campylobacter*, and *Escherichia*  
8 *coli* bacteria. Overcrowded and mixed livestock practices, as well as the trade in  
9 bushmeat, can facilitate interspecies host transfer of disease agents, leading to dangerous  
10 novel pathogens such as SARS and new strains of influenza.

11       **Scenarios**

- 12       ▪ Tropical developing countries are more likely to be affected in the future due to the greater  
13 exposure of people in these countries to vectors of infectious disease transmission. Such  
14 populations have a scarcity of resources to respond to disease and to plan environmental  
15 modifications associated with economic activities (*high certainty*). However, international  
16 trade and transport leave no country entirely unaffected (S11).
- 17       ▪ The health consequences under the MA scenarios related to changes in the disease regulation  
18 service of ecosystems vary widely, with some scenarios showing improving conditions and  
19 others declining conditions (S11).

20       **Appendix Table A.3. Importance of Infectious Diseases as Related to Ecosystem**  
21 **Changes (+ = low; ++ = moderate; +++ high; ++++ = very high) (C14, Table 14.4)**  
22

Disease	Cases Per Year <sup>a</sup>	Disability-adjusted Life Years <sup>b</sup> (thousands)	(Proximate) Emergence Mechanism	(Ultimate) Emergence Driver	Geographical Distribution	Expected Variation From Ecological Change	Confidence Level
Malaria	350 m	46,486	niche invasion; vector expansion	deforestation; water projects	tropical (America, Asia, and Africa)	++++	+++
Dengue fever	80 m	616	vector expansion	urbanization; poor housing conditions	tropical	+++	++

# 1 Waste Treatment

## Regulating Services

2 Because the characteristics of both wastes and receiving ecosystems vary, environments vary in  
3 their ability to absorb wastes and to detoxify, process, and sequester them. Some contaminants  
4 (such as metals and salts) cannot be converted to harmless materials, but others (organic  
5 chemicals and pathogens, for example) can be degraded to harmless components. Nevertheless,  
6 these materials may be released to the environment fast enough to modify ecosystem functioning  
7 significantly. Some materials (such as nutrient fertilizers and organic matter) are normal  
8 components of organism metabolism and ecosystem processes. Nevertheless, loading rates of  
9 these materials may occur fast enough to modify and impair ecosystem function significantly.

### 10 Condition and Trends

- 11 ▪ The problems associated with wastes and contaminants are in general growing. Some  
12 wastes—sewage, for instance—are produced in nearly direct proportion to population size.  
13 Other types of wastes and contaminants reflect the affluence of society. An affluent society  
14 uses and generates a larger volume of waste-producing materials such as domestic trash and  
15 home-use chemicals (C15.ES).
- 16 ▪ Where there is significant economic development, loadings of certain wastes are expected to  
17 increase faster than population growth. The generation of some wastes (industrial waste, for  
18 example) does not necessarily increase with population or development state. These wastes  
19 may often be reduced through regulation aimed to encourage producers to clean discharges or  
20 to seek alternate manufacturing processes C15.ES).
- 21 ▪ In developing countries, 90–95% of all sewage and 70% of industrial wastes are dumped  
22 untreated into surface water (C7.4.5). Regional patterns of processing nitrogen loads in  
23 freshwater ecosystems provide a clear example of the overloading of the waste processing  
24 service of ecosystems.
- 25 ▪ Aquatic ecosystems “cleanse” on average 80% of their global incident nitrogen loading but  
26 this intrinsic self-purification capacity of these ecosystems varies widely and is not unlimited  
27 (C7.2.5).
- 28 ▪ Severe deterioration in the quality of fresh water is magnified in cultivated and urban systems  
29 (high use, high pollution sources) and in dryland systems (high demand for flow regulation,  
30 absence of dilution potential) (C7.ES).

### 31 Scenarios

- 32 ▪ It is neither possible nor appropriate to attempt to state whether the intrinsic waste  
33 detoxification capabilities of the planet as a whole will increase or decrease with a changing  
34 environment. The detoxification capabilities of individual locations may change with  
35 changing conditions (such as changes in soil moisture levels). At high waste-loading rates,  
36 however, the intrinsic capability of environments is overwhelmed, such that wastes will build  
37 up in the environment to the detriment of human well-being and a loss of biodiversity  
38 (C15.ES).
- 39 ▪ The service of water purification could be either enhanced or degraded in both developing and  
40 industrial countries under the MA Scenarios (S9.5.4). Within industrial countries, the dilution  
41 capacity of most rivers increases because higher precipitation leads to increases in runoff in  
42 most river basins. Wetland areas decrease because of the expansion of population and  
43 agricultural land. Wastewater flows increase, but in some scenarios the wealth of the North

1 enables it to repair breakdowns in water purification as they occur. Within developing  
2 countries, the pace of ecosystem degradation, the overtaxing of ecosystems by high waste  
3 loads, and the decline of wetland area because of the expansion of population and agricultural  
4 land tend to drive a deterioration of water purification in two scenarios. The *Adapting Mosaic*  
5 scenario, however, could lead to some gains in water purification even in developing  
6 countries, and the *TechnoGarden* scenario would also result in gains.

2 Ecosystems play important roles in modulating the effects of extreme events on human systems.  
3 Ecosystems affect both the probability and severity of events, and they modulate the effects of  
4 extreme events. Soils store large amounts of water, facilitate transfer of surface water to  
5 groundwater, and prevent or reduce flooding. Barrier beaches, wetlands, and lakes attenuate  
6 floods by absorbing runoff peaks.  
7

## 8 Condition and Trends

- 9     ▪ Humans are increasingly occupying regions and localities that are exposed to extreme events,  
10     (such as on coasts and floodplains or close to fuelwood plantations). These actions are  
11     exacerbating human vulnerability to extreme events, such as the December 2004 tsunami in  
12     the Indian Ocean. Many measures of human vulnerability show a general increase due to  
13     growing poverty, mainly in developing countries (C16.ES).
- 14     ▪ Roughly 17% of all the urban land in the United States is located in the 100-year flood zone.  
15     Likewise, in Japan about 50% of the population lives on floodplains, which cover only 10%  
16     of the land area. In Bangladesh, the percentage of flood-prone areas is much higher and  
17     inundation of more than half of the country is not uncommon. For example, about two thirds  
18     of the country was inundated in the 1998 flood (C16.2.2).
- 19     ▪ Many of the available datasets on extreme events show that impacts are increasing in many  
20     regions around the world. From 1992 to 2001, floods were the most frequent natural disaster  
21     (43% of 2,257 disasters), and they killed 96,507 people and affected more than 1.2 billion  
22     people over the decade. Annual economic losses from extreme events increased tenfold from  
23     the 1950s to the 1990s (C16.ES).
- 24     ▪ The loss of ecosystems such as wetlands and mangroves has significantly reduced natural  
25     mechanisms of protection from natural hazards. For example, forested riparian wetlands  
26     adjacent to the Mississippi River in the United States during presettlement times had the  
27     capacity to store about 60 days of river discharge. With the removal of wetlands through  
28     canalization, leveeing, and draining, the remaining wetlands have a storage capacity of less  
29     than 12 days discharge—an 80% reduction of flood storage capacity (C16.1.1).
- 30     ▪ The number of floods and fires increased significantly on all continents over the past 60 years.  
31     (See Appendix Figures A.7 and A.8.)
- 32     ▪ Within industrial countries, the area burned by fires is declining but the number of major fires  
33     is increasing. In the United States, for example, the area burned has declined by more than  
34     90% since 1930, while in Sweden the area burned annually fell from about 12,000 hectares in  
35     1876 to about 400 hectares in 1989. In North America, however, the number of fire  
36     “disasters”—10 or more people reportedly killed, 100 people reportedly affected, a declared  
37     state of emergency, and a call for international assistance—increased from about 10 in the  
38     1980s to about 45 during the 1990s (C16.2.2).

 6 **1900s**  
 7 (C16, Fig 16.9)

8  
 9

Human cultures, knowledge systems, religions, social interactions, and amenity services have been influenced and shaped by the nature of an ecosystem. At the same time, humankind has influenced and shaped its environment to enhance the availability of certain valued services. Recognizing that it is not possible to fully separate the different spiritual, intellectual, and physical links between human cultures and ecosystems, the MA assessed six main types of cultural and amenity services provided by ecosystems: cultural diversity and identity; cultural landscapes and heritage values; spiritual services; inspiration (such as for arts and folklore); aesthetics; and recreation and tourism. Because global aggregated information on the condition of cultural services was limited (with the partial exception of recreational and tourism benefits), the section below draws significantly on information in the MA sub-global assessments.

## Condition and Trends

- Transformation of once diverse ecosystems into relatively more similar cultivated landscapes, combined with social and economic changes including rapid urbanization, breakdown of extended families, loss of traditional institutions, easier and cheaper transportation, and growing economic and social “globalization,” has significantly weakened the linkages between ecosystems and cultural diversity and cultural identity (C17.2.1). Throughout human evolution, human societies have developed in close interaction with the natural environment, which has shaped their cultural identity, value systems, and language.
- The loss of particular ecosystem attributes (sacred species or sacred forests), combined with social and economic changes, can sometimes weaken the spiritual benefits people obtain from ecosystems in many parts of the world (C17.2.3). On the other hand, under some circumstances (such as where ecosystem attributes are causing significant threats to people) the loss of some attributes may enhance spiritual appreciation for what remains.
- People across cultures and regions express, in general, an aesthetic preference for natural environments over urban or built ones; the conversion and degradation of relatively natural environments has diminished these benefits. Ecosystems continue to inspire arts, songs, drama, dance, design, and fashion, although the stories told through such media are different from those told historically (C17.2.5).
- Recreation and tourism uses of ecosystems are growing, due to growing populations, greater leisure time available among wealthy populations, and greater infrastructure development to support recreational activities and tourism. Nature travel increased at an estimated rate of 10–30% annually in the early 1990s, and in 1997 nature tourism accounted for approximately 20% of total international travel (C17.2.6). Tourism is now the primary economic development strategy for a number of developing countries.
- Tourism is an important component of the economies of many of the MA sub-global assessment study areas, and at all scales most stakeholders of assessments requested its inclusion. In contrast, spiritual, religious, recreational, and educational services tended to be assessed only at a fine scale in small local studies, typically because the data required for these assessments are not available at a broad scale as well as because of the culture-specific, intangible, and sometimes sensitive nature of these services (SG8.3).
- Within the MA sub-global assessments, cultural services of tourism and recreation were generally in a good condition and growing, although some assessments expressed concerns about tourist activities potentially reducing the capacity of ecosystems to provide this cultural service (SG8.3).

- 1     ▪ In contrast, within the MA sub-global assessments local-scale services of a spiritual nature are  
2     of a variable condition, typically either collapsing or being revived, depending on policies,  
3     interventions, and context-specific factors such as changes in leadership (SG8.3). Spiritual  
4     values were found to act as strong incentives for ecosystem conservation in sub-global  
5     assessments in Peru, Costa Rica, India, and some parts of Southern Africa. Educational  
6     services of ecosystems assessed in Sweden, São Paulo, and Portugal are all increasing due to  
7     growing levels of awareness of the value and benefits of, and thus the demand for,  
8     environmental education.
- 9     ▪ While provisioning services such as water, medicinal plants, fuelwood, and food are very  
10    important, spiritual and sacred elements in the local landscape also have a very specific and  
11    important value to local people across all the assessments. In several cases, spiritual values  
12    coincided with other values, such as biodiversity, water supply, biomedicines, and fuel  
13    (SG11.3).

14    **Scenarios**

- 15    ▪ The MA Scenarios project changes in cultural services based only on a qualitative analyses  
16    due to the absence of suitable quantitative models. Cultural services increase in some  
17    scenarios and decline in others, indicating that our path into the future could have  
18    considerable impact on the provision of cultural services. Generally, cultural services decline  
19    moderately in *Global Orchestration* and strongly in *Order from Strength*, driven in both cases  
20    by lack of personal experience with nature and lower cultural diversity. Lower cultural  
21    diversity also drives a decline in cultural services in the *TechnoGarden* scenario. On the other  
22    hand, cultural services increase in *Adapting Mosaic*, which can be seen in the marked increase  
23    in knowledge systems and cultural diversity (S9.7).

24  
25

# 1 Nutrient Regulation

## Supporting Services

2 An adequate and balanced supply of elements necessary for life, provided through the ecological  
3 processes of nutrient cycling, underpins all other ecosystem services. The cycles of several key  
4 nutrients have been substantially altered by human activities over the past two centuries, with  
5 important positive and negative consequences for a range of other ecosystem services and for  
6 human well-being. Nutrients are mineral elements such as nitrogen, phosphorus, and potassium  
7 that are essential as raw materials for organism growth and development. Ecosystems regulate the  
8 flows and concentrations of nutrients through a number of complex processes that allow these  
9 elements to be extracted from their mineral sources (atmosphere, hydrosphere, or lithosphere) or  
10 recycled from dead organisms. This service is supported by a diversity of different species.

### 11 Condition and Trends

- 14 ■ The capacity of terrestrial ecosystems to absorb and retain the nutrients supplied to them  
15 either as fertilizers or from the deposition of airborne nitrogen and sulfur has been  
16 undermined by the radical simplification of ecosystems into large-scale, low-diversity  
17 agricultural landscapes. Excess nutrients leak into the groundwater, rivers, and lakes and are  
18 transported to the coast. Treated and untreated sewage released from urban areas adds to the  
19 load. (C.SDM)
  
- 20 ■ In preindustrial times, the annual flux of nitrogen from the atmosphere to the land and aquatic  
21 ecosystems was roughly 110–210 teragrams of nitrogen a year. Human activity contributes  
22 an additional 165 teragrams or so of nitrogen per year, roughly doubling the rate of creation of  
23 reactive N on the land surfaces of Earth (R9.2). (See Appendix Figure A.9.)
  
- 24 ■ The N accumulation on land and in waters has permitted a large increase in food production  
25 in some countries, but at the cost of increased emissions of greenhouse gases and frequent  
26 deterioration in freshwater and coastal ecosystem services, such as water quality, fisheries,  
27 and amenity values (C12.ES).
  
- 28 ■ Phosphorus is also accumulating in ecosystems at a rate of 10.5–15.5 teragrams per year,  
29 compared with a preindustrial rate of 1–6 teragrams per year, mainly as a result of the use of  
30 phosphorus (obtained through mining) in agriculture. Most of this accumulation is in soils. If  
31 these soils erode into freshwater systems, deterioration of ecosystem services can result. This  
32 tendency is likely to spread and worsen over the next decades, since large amounts of P have  
33 been accumulated on land and their transport to water systems is slow and difficult to prevent  
34 (C12.ES).
  
- 35 ■ Sulfur emissions have been progressively reduced in Europe and North America but not yet in  
36 the emerging industrial areas of the world: China, India, South Africa, and the southern parts  
37 of South America. A global assessment of acid deposition threats suggests that tropical  
38 ecosystems are at high risk (C12.ES).
  
- 39 ■ Human actions at all scales required to feed the current world population have increased the  
40 “leakiness” of ecosystems with respect to nutrients. Tillage often damages soil structure, and  
41 the loss of biodiversity may increase nutrient leaching. Simplification of the landscape and  
42 destruction of riparian forests, wetlands, and estuaries allow unbuffered flows of nutrients  
43 between terrestrial and water ecosystems. Specific forms of biodiversity are critical to  
44 performing the buffering mechanisms that ensure the efficient use and cycling of nutrients in  
45 ecosystems (C12.ES).

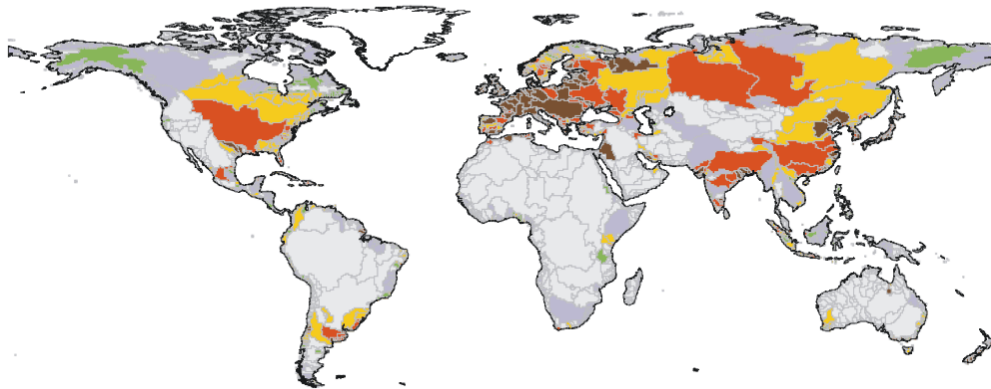

- 1     ▪ In contrast to these issues associated with nutrient oversupply, there remain large parts of  
2     Earth, notably in Africa and Latin America, where harvesting without nutrient replacement  
3     has led to a depletion of soil fertility, with serious consequences for human nutrition and the  
4     environment (C12.ES).

5     **Scenarios**

- 6     ▪ Recent scenario studies that include projections of nitrogen fertilizer use indicate an increase  
7     of between 10% and 80% (or more) by 2020 (S9.3.7).  
8
- 9     ▪ The MA scenarios project the global flux of nitrogen to coastal ecosystems to increase by 10–  
10    20% by 2030. River nitrogen will not change in most industrial countries, while a 20–30%  
11    increase is projected for developing countries. This is a consequence of increasing nitrogen  
12    inputs to surface water associated with urbanization, sanitation, development of sewerage  
13    systems, and lagging wastewater treatment, as well as increasing food production and  
14    associated inputs of nitrogen fertilizer, animal manure, atmospheric nitrogen deposition, and  
15    biological nitrogen fixation in agricultural systems. Growing river nitrogen loads will lead to  
16    increased incidence of problems associated with eutrophication in coastal seas. (S9.3.7)  
17

1 **Appendix Figure A.9. Contrast between Contemporary and Pre-disturbance Transports of**  
2 **Total Nitrogen through Inland Aquatic Systems Resulting from Anthropogenic Acceleration**  
3 **of This Nutrient Cycle.** (C7 Fig 7.5) While the peculiarities of individual pollutants, rivers, and  
4 governance define the specific character of water pollution, the general patterns observed for  
5 nitrogen are representative of anthropogenic changes to the transport of waterborne constituents.  
6 Elevated contemporary loadings to one part of the system (such as croplands) often reverberate to  
7 other parts of the system (to coastal zones, for example), exceeding the capacity of natural  
8 systems to assimilate additional constituents.

# 1 Appendix B. Effectiveness of Assessed Responses

2 A response is considered to be *effective* when its assessment indicates that it has enhanced the  
 3 particular ecosystem service (or, in the case of biodiversity, its conservation and sustainable use)  
 4 without significant harm to other ecosystem services. A response is considered *promising* either  
 5 if it does not have a long track record to assess but appears likely to succeed or if there are known  
 6 means of modifying the response so that it can become effective. A response is considered  
 7 *problematic* if its historical use indicates either that it has not met the goals related to service  
 8 enhancement (or conservation and sustainable use of biodiversity) or that it has caused significant  
 9 harm to other ecosystem services. Labeling a response as *effective* does not mean that the  
 10 historical assessment has not identified problems or harmful trade-offs. Such trade-offs almost  
 11 always exist, but they are not considered significant enough as to negate the effectiveness of the  
 12 response. Similarly, labeling a response as *problematic* does not mean that there are no promising  
 13 opportunities to reform the response in a way that can meet its policy goals without undue harm to  
 14 ecosystem services.

15 The typology of response presented in the Table in this Appendix is defined by the nature of  
 16 intervention, classified as following: institutional and legal (I), economic and incentives (E),  
 17 social and behavioral (S), technological (T), and knowledge and cognitive (K). Note that the  
 18 dominant class is given in the Table. The actors who make decisions to implement a response are  
 19 governments at different levels, such as international (GI) (mainly through multilateral  
 20 agreements or international conventions), national (GN), and local (GL); the business/industry  
 21 sector (B); and civil society, which includes nongovernmental organizations (NGO), community-  
 22 based and indigenous peoples organizations (C), and research institutions (R). The actors are not  
 23 necessarily equally important.

24 The table includes responses assessed for a range of ecosystem services—food, fresh water,  
 25 wood, nutrient management, flood and storm control, disease regulation, and cultural services. It  
 26 also assesses responses for biodiversity conservation, integrated responses, and responses  
 27 addressing one specific driver: climate change.

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
<b>Biodiversity conservation and sustainable use</b>						
Protected areas (PA)				PAs are an extremely important in biodiversity and ecosystem conservation programs, especially in sensitive environments that contain valuable biodiversity components. At global and regional scale, existing PAs are essential but not sufficient to conserve the full range of biodiversity. PAs need to be better located, designed, and managed to ensure representativeness and to deal with the impacts of human settlement within PAs, illegal harvesting, unsustainable tourism, invasive species and climate change. They also need a landscape approach that includes protection outside of PAs (R5)	I	GI GN GL NGO C R
Helping Local People to Capture Biodiversity Benefits				Providing incentives for biodiversity conservation in the form of benefits for local people (e.g. through products from single species or from ecotourism) has proved to be very difficult. Programs have been more successful when local communities have been in a position to make management decisions consistent with overall biodiversity conservation. "Win-win" opportunities for biodiversity conservation and benefits for local communities exist, but local communities can often achieve greater benefits from actions that lead to biodiversity loss. (R5)	E	GN GL B NGO C

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
Promoting better management of wild species as a conservation tool, including ex situ conservation	Green			More effective management of individual species should enhance biodiversity conservation and sustainable use. "Habitat-based" approaches are critical, but they can not replace "species-based" approaches. Zoos, botanical gardens and other ex situ programs build support for conservation, support valuable research, and provide cultural benefits of biodiversity. (R5)	T S	GN S NGO R
Integrating biodiversity into regional planning	Green			Integrated regional planning can provide a balance among land uses that promotes effective trade-offs among biodiversity, ecosystem services, and other needs of society. Great uncertainty remains as to what components of biodiversity persist under different management regimes, limiting the current effectiveness of this approach. (R5)	I	GN GL NGO
Encouraging private sector involvement in biodiversity conservation		Yellow		Many companies are preparing their own biodiversity action plans, managing their landholdings in ways that are more compatible with biodiversity conservation, supporting certification schemes that promote more sustainable use, and accepting their responsibility for addressing biodiversity issues. The business case that has been made for larger companies needs to be extended to other companies as well. (R5)	I	NG B NGO R
Including biodiversity issues in agriculture, forestry and fisheries		Yellow		More diverse production systems can be as effective as low-diversity systems, or even more effective. And strategies based on more intensive production rather than on the expansion of the area allow for better conservation. (R5)	T	NG B
Designing governance approaches to support biodiversity		Yellow	Red	Decentralization of biodiversity management in many parts of the world has had variable results. The key to success is strong institutions at all levels, with secure tenure and authority at local levels essential to providing incentives for sustainable management. (R5)	I	GI GN GL R
Promoting international cooperation through Multilateral Environmental Agreements (MEAs)		Yellow		MEAs should serve as an effective means for international cooperation in the areas of biodiversity conservation and sustainable use. They cover the most pressing drivers and issues related to biodiversity loss. Additional MEAs are not required, but better coordination between conventions would increase their usefulness. (R5,15)	I	GI GN
Environmental education and communication	Green			Education and communication programs have both informed and changed preferences for biodiversity conservation and have improved implementation of biodiversity responses. Providing the human and financial resources to undertake effective work in this area is a continuing barrier. (R5)	S	GN GL NGO C
Globalization, trade, and domestic and International policies on food		Yellow	Red	Government policies related to food production (price supports and various types of payments, or taxes) can have adverse economic, social and environmental effects. (R6)	E	GI GN B
Knowledge and education	Green	Yellow		Further research can make food production socially, economically and environmentally sustainable. Public education should enable consumers to make informed choices about nutritious, safe and affordable food. (R6)	S K	GN GL NGO C
Technological responses, including biotechnology, precision agriculture and organic farming		Yellow		New agricultural sciences and effective natural resource management could support a new agricultural revolution to meet world-wide food needs. This would help environmental, economic and social sustainability. (R6)	T	GN B R
Water management		Yellow		Emerging water pricing schemes and water markets indicate that water pricing can be a means for efficient allocation and responsible use. (R6)	E	GN GL B NGO
Fisheries management		Yellow	Red	Strict regulation of marine fisheries, especially in the area of fishing quotas and fishing capacity reduction, is urgently needed. Given the potential detrimental environmental impacts of aquaculture,	I E	GN GL B

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
				appropriate regulatory mechanisms need to supplement existing polices. (R6)		NGO
Livestock management				Livestock polices need to be reoriented in view of problems concerning overgrazing and dry land degradation, rangeland fragmentation and loss of wildlife habitat, dust formation, bush encroachment, deforestation, nutrient overload through disposal of manure, and greenhouse gas emissions. Policies also need to focus on human health issues related to diseases such as bird flu and BSE. (R6)	T	GN B
Recognition of gender issues				Response polices need to be gender sensitive and designed to empower women by providing knowledge and ensuring access to and control of resources necessary for food security. This needs to be based on a systematic analysis of gender dynamics and explicit consideration of relationships between gender and food and water security. (R6)	S	GN NGO C
Determining ecosystem water requirements				In order to balance competing demands, it is critical that society explicitly agrees on ecosystem water requirements (environmental flows). (R7)	I T	GN GL NGO R
Rights to freshwater services and responsibilities for their provision				Both public and private ownership systems of fresh water, and of the land resources associated with its provision, have largely failed to create incentives for provision of water services. As a result, upland communities have generally been excluded from access to benefits, particularly when they lack tenure security, and have resisted regulations regarded as unfair. Effective property rights systems with clear and transparent rules can increase stakeholders' confidence that they will have access to the benefits of freshwater services and, therefore, willingness to pay for them. (R7)	I	GN B C
Increasing the effectiveness of public participation in decision-making				Degradation of freshwater and other ecosystem services have a disproportionate impact on those excluded from participation in decision-making. Key for improving participatory processes are to increase the transparency of information, improve the representation of marginalized stakeholders, engage them in the establishment of policy objectives and priorities for the allocation of freshwater services, and create space for deliberation and learning that accommodates multiple perspectives. (R7)	I	GN GL NGO C R
River Basin Organizations (RBOs)				RBOs can play an important role in facilitating cooperation and reducing transaction costs of large-scale responses. RBOs are constrained or enabled primarily by the degree of stakeholder participation, their agreement on objectives and management plans, and their cooperation on implementation. (R7)	I	GI GN NGO
Regulatory responses				Regulatory approaches based on market-based incentives (e.g. damages for exceeding pollution standards) are suitable for point-source pollutants. Regulatory approaches that simply outlaw particular types of behavior can be unwieldy and burdensome, and may fail to provide incentives for protecting freshwater services. (R7)	I	GN GL
Water markets				Economic incentives can potentially unlock significant supply- and demand-side efficiencies while providing cost-effective reallocation between old (largely irrigation) and new (largely municipal and instream) uses. (R7)	E	GI GN B
Payments for watershed services				Payments for ecosystem services provided by watersheds have narrowly focused on the role of forests in the hydrological regime. They should be based on the entire flow regime, including consideration of the relative values of other land cover and land uses, such as wetlands, riparian areas, steep slopes, roads, and management practices. Key challenges for payment schemes are capacity building for place-based monitoring and assessment, identifying services in the context of the entire flow regime,	E	GN B C

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
				considering trade-offs and conflicts among multiple uses, and making uncertainty explicit. (R7)		
Partnerships and financing				There is a clear mismatch between the high social value of freshwater services and the resources allocated to manage water. Insufficient funding for water infrastructure is one manifestation of this. Focusing only on large-scale privatization to improve efficiency and cost-recovery has proven a double-edged strategy – price hikes or control over resources have created controversy and, in some cases, failure and withdrawal. Development of water infrastructure and technologies must observe best practices to avoid problems and inequities. The re-examination and retrofitting/refurbishment of existing infrastructure is the best option in the short and medium term. (R7)	I E	GI GN B NGO C
Large dams				The impact of large dams on freshwater ecosystems is widely recognized as being more negative than positive. In addition, the benefits of their construction have rarely been shared equitably – the poor and vulnerable and future generations often fail to receive the social and economic benefits from dams. Pre-construction studies are typically overly optimistic about the benefits of projects and underestimate costs. (R7)	T	GN
Wetland restoration				Challenges exist in relation to when is necessary to create and restore wetlands: what combination of processes leads to a desired combination of wetland structure and function. It is unlikely that created wetlands can structurally and functionally replace natural wetlands. (R7)	T	GN GL NGO B
International forest policy processes and development assistance				International forest policy processes have made some gains within the forest sector. Attention should be paid to integration of agreed forest management practices in financial institutions, trade rules, global environment programs and global security decision-making. (R8)	I	GI GN B
Trade liberalization				Forest product trade tends to concentrate decision making power (and benefits from) forest management, rather than spreading it to include poorer and less powerful players. It “magnifies” the effect of governance, making good governance better and bad governance worse. Trade liberalization can stimulate a “virtuous cycle” if the regulatory framework is robust and externalities are addressed. (R8)	E	GI GN
National forest governance initiatives and national forest programs				Forest governance initiatives and country-led national forest programs show promise for integrating ecosystem health and human well-being where they are negotiated by stakeholders and strategically focused. (R8)	I	GN GL
Direct management of forests by indigenous peoples				Indigenous control of traditional homelands is often presented as having environmental benefits, although the main justification continues to be based on human and cultural rights. Little systematic data exist, but preliminary findings on vegetation cover and forest fragmentation from the Brazilian Amazon, suggests that an indigenous control area is at least as effective as a strict-use protected area. (R8)	I	GL C
Collaborative forest management and local movements for access and use of forest products				Government-community collaborative forest management can be highly beneficial but has had mixed results. Programs have generated improved resource management and access of the rural poor to forest resources, but have fallen short in their potential to benefit the poor. Local responses to problems of access and use of forest products have proliferated in recent years. They are collectively more significant than efforts led by governments or international processes but require their support to spread. (R8)	I	GN GL B NGO C
Small-scale private and public-private ownership				Small private ownership of forests can deliver more local economic benefits and better forest management than ownership by larger corporate bodies where information, tenure and capacity are strong.	I	GL B C

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
and management of forests				(R8)		
Company-community forestry partnerships				Company–community partnerships can be better than solely corporate forestry, or solely community or small-scale farm forestry, in delivering benefits to the partners and the public at large. (R8)	I	GL B C
Public and consumer action				Public and consumer action has resulted in important forest and trade policy initiatives and improved practices in large forest corporations. This has had an impact in “timber consuming countries” and in international institutions. The operating standards of some large corporations and institutions, as well as of those whose non-forest activities have an impact on forests, have been improved. (R8)	S	NGO B C
Third-party voluntary forest certification				Forest certification has become widespread; however, most certified forests are in the North, managed by large companies and exporting to Northern retailers. The early drivers of certification hoped it would be an effective response to tropical deforestation. (R8)	I E	B
Wood technology and biotechnology				Wood technology responses have focused on industrial plantation species with properties suited for manufactured products. (R8)	T	NG R B
Commercialization of non-timber forest products (NTFP)				Commercialization of NTFP has had modest impacts on local livelihoods and had not always created incentives for conservation. An increased value of NTFPs is not always an incentive for conservation and can have the opposite effect. Incentives for sustainable management of NTFPs should be reconsidered, including exploration of joint-production of timber and NTFP. (R8)	E	NGO B R
Natural forest management in the tropics				To be economic, sustainable natural forest management in the tropics must focus on a range of forest goods and services, not just timber. The “best practices” of global corporations should be assessed, exploring at the same time “what works” in traditional forest management and the work of local (small) enterprises. Considerable interest has developed in the application of reduced impact logging, especially in tropical forests, which lowers environmental impacts and can also be more efficient and cost-effective. (R8)	T	GI GN GL B NGO C
Forest plantation management				Farm woodlots and large-scale plantations are becoming a response to growing wood demand and declining natural forest areas. Without adequate planning and management, forest plantations can be in established in the wrong sites, with the wrong species and provenances. In degraded lands, afforestation may deliver economic, environmental, and social benefits to communities and help in reducing poverty and enhancing food security. (R8)	T	GN GL B NGO R
Fuelwood management				Fuelwood remains one of the main products of the forest sector in the South. If technology development continues, the industrial-scale forest product fuels could become a major sustainable energy source. (R8)	T	GL B C
Afforestation and reforestation for carbon management				Although many early initiatives were based on forest conservation or management, afforestation activities now predominate, perhaps reflecting the international decisions in 2001 to allow only afforestation and reforestation activities into the Clean Development Mechanism (CDM) for the first commitment period. (R8)	T E	GI GN B
Regulations				Mandatory policies, including regulatory control and tax or fee systems, place the costs and burden of pollution control on the polluter. Technology-based standards are easy to implement but may discourage innovation and are generally not seen as cost-effective. (R9)	I	GI GN
Market based instruments				Market-based instruments, such as financial incentives, subsidies and taxes, hold potential for better nutrient management, but may not be relevant in all countries and circumstances. Relatively little is	E	GN B R

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
				known empirically about the impact of these instruments on technological change. (R9)		
Hybrid approaches				Combinations of regulatory, incentive, and market-based mechanisms are possible for both national and watershed-based approaches and may be the most cost-effective and politically acceptable (R9)	I E	GI GN GL NGO C, R
Physical structures				Historically, emphasis was on physical structures/measures over natural environment and social institutions. This choice often creates a false sense of security, encouraging people to accept high risks. Evidence indicates that more emphasis needs to be given to the natural environment and nonstructural measures. (R11)	T	GN B
Use of natural environment				Flood and storm impacts can be lessened through maintenance and management of vegetation and through natural or manmade geomorphological features (natural river channels, dune systems, terrace farming). (R11)	T	GN GL NGO C
Information, institutions and education				These approaches emphasize disaster preparedness, disaster management, flood and storm forecasting, early warning, evacuation. These programs are vital for reducing losses. (R11)	S I	GN GL B C
Financial services				These responses emphasize insurance, disaster relief and aid. Both social programs and private insurance are important coping mechanisms for flood disaster recovery. They can, however, inadvertently contribute towards community vulnerability by encouraging development within floodplains or by creating cultures of entitlement. (R11)	E	GN B
Land-use planning				Land-use planning a process of determining the most desirable type of land-use. It can help to mitigate disasters and reduce risks by avoiding development in hazard prone areas. (R11)	I	GN
Integrated vector management (IVM)				Reducing the transmission of infectious diseases often has effects on other ecosystem services. IVM enable a coordinated response to health and the environment. IVM use targeted interventions to remove or control vector-breeding sites, disrupt vector lifecycles, and minimize vector-human contact, while minimizing effects on other ecosystem services. IVM is most effective when integrated with socioeconomic development. (R12)	I	GN NGO
Environmental management/modification to reduce vector and reservoir host abundance				Environmental management and biological and chemical interventions can be highly cost-effective and entail very low environmental impacts. Crucially, well-targeted environmental management techniques can be highly cost-effective. (R12)	I	GN B C R
Biological control/natural predators				Environmental management and biological and chemical interventions can be highly cost-effective and entail very low environmental impacts. Biological control may be effective if breeding sites are well known and limited in number but less feasible where these are numerous. (R12)	T	GN B R
Chemical control				Environmental management and biological and chemical interventions can be highly cost-effective and entail very low environmental impacts. Insecticides remain an important tool and their selective use is likely to continue within IVM. However, there are concerns regarding the impacts of insecticides, especially persistent organic pollutants, on the environment and on human populations, particularly insecticide sprayers. (R12)	T	GN B R
Human settlement patterns				The most basic management of human-vector contact is through improvements in the placement and construction of housing. (R12)	T	GN NGO C

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
Health awareness and behavior				Social and behavioral responses can help control vector-borne disease while also improving other ecosystem services. (R12)	S	C
Genetic modification of vector species to limit disease transmission				New “cutting-edge” interventions, such as transgenic techniques, could be available within the next 5-10 years. However, consensus is lacking in the scientific community on the technical feasibility and public acceptability of such an approach. (R12)	T	GN B NGO R
Awareness of the global environment and linking local and global institutions				Awareness of the globe working as a system has led to an integrated approach to ecosystems. This process has emphasized the “human environment” concept and the discussion of environmental problems at a global scale. Local organizations also take advantage of emerging global institutions and conventions to bring their case to wider political arenas. (R14)	S I	GI GN GL
From restoring landscapes to valuing cultural landscapes				Landscapes are subject to and influenced by cultural perceptions and political and economic interests. This influences decisions on landscape conservation. (R14)	S K	GL NGO C
Recognizing sacred areas				While linking sacred areas and conservation is not new, there has been an increase in translating “the sacred” into legislation or legal institutions granting land rights. This requires extensive knowledge about the link between the sacred, nature, and society in a specific locale. (R14)	S	GL NGO C
International agreements and conservation of biological, and agro-pastoral diversity				Increased exploitation and awareness concerning the disappearance of local resources and knowledge has highlighted the need to protect local and indigenous knowledge. Some countries have adopted specific laws, policies and administrative arrangements emphasizing the concept of prior informed consent of knowledge-holders. (R14)	I	GI GN
Integrating local and indigenous knowledge				Local and indigenous knowledge evolves in specific contexts and good care should be taken to not de-contextualize it. Conventional “best-practices” methods focusing on content may not be appropriate to deal with local/indigenous knowledge. (R14)	K I	GN B NGO
Compensating for knowledge				Compensation for the use of local and indigenous knowledge by third parties is an important, yet complicated response. The popular idea that local and indigenous knowledge can be promoted by strengthening “traditional” authorities may not be valid in many cases. (R14)	E K	GN B C
Property right changes				Communities do need control over natural resources. Traditional leadership may not always be the solution. Local government institutions that are democratically elected and have real authority over resources may be in some cases a better option. There is a tendency to shift responsibilities back and forth between “traditional” authorities and local government bodies, without giving any of them real decision-making powers. (R14)	I	GN GL C
Certification programs				This is a promising response, but many communities do not have access to it or are not aware of their existence. In addition, the financial costs involved reduce the chances for local communities to participate independently. (R14)	I S	GI GN B
Fair trade				Fair trade is a movement initiated to help disadvantaged or politically marginalized communities, by paying better prices and providing better trading conditions, along with raising consumers’ awareness of their potential role as buyers. Fair trade overlaps in some cases with initiatives focusing on the environmental performance of trade. (R14)	E S	GI GN GL NGO C
Eco-tourism and cultural tourism				Eco-tourism can provide economic alternatives to value eco-systems services. There may be potential conflicts in resource use and the aesthetics of certain ecosystems. Different ecosystems are subjected to different types and scales of impact from tourism infrastructures. Furthermore, some ecosystems are easier to market to tourists than others. The market value of ecosystems may vary according to	E	GL B C

Response	Effective-ness			Notes	Type of Response	Required actors
	Effective	Promising	Problematic			
				public perceptions of nature. Freezing of landscapes, conversion of landscapes, dispossession, and removing of human influences may result, depending on views of what eco-tourism should represent. Yet, when conservation receives no budgetary subsidy, tourism can provide revenues for conservation. (R14)		
International environmental governance				Environmental policy integration at the international level is almost exclusively dependent on governments' commitment to binding compromises on given issues. Major challenges include reform of the international environmental governance structure and coherence between international trade and environment mechanisms. (R15)	I E K T B	GI GN
National action plans and strategies aiming to integrate environmental issues into national policies				Examples include National Conservation Strategies (NCS), National Environmental Action Plans (NEAP) and National Strategies for Sustainable Development (NSSD). Success depends on enabling conditions such as ownership by governments and civil society, broad participation, both across sectors within the government and with the private sector, and at the sub-national and local scales. The national integrated responses may be a good starting point for cross-departmental linkages in governments. They may initiate a consultation process and the development of skills and capacity for further integrated responses. (R15)	I E K T B	GN GL B NGO C
Sub-National, local scale integrated approaches				Many integrated responses are implemented at the sub-national level, and examples include Sustainable Forest Management (SFM), Integrated Coastal Zone Management (ICZM), Integrated Conservation and Development Programs (ICDP) and Integrated River Basin Management (IRBM). Results so far have been varied, and a major constraint experienced by sub-national and multi-scale responses is the lack of implementation capacity. (R15)	I E K T B	GN GL NGO C
<b>Climate change</b>						
UN Framework Convention on Climate Change (UNFCCC) and Kyoto Protocol				The ultimate goal of UNFCCC is stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. The Kyoto Protocol contains binding limits on greenhouse gas emissions on industrialized countries who agreed to reduce their emissions by an average of about 5% between 2008-2012 relative to the levels emitted in 1990. (R13)	I	GI GN
Reductions in net greenhouse gas emissions				Significant reductions in net greenhouse gas emissions are technically feasible, in many cases at little or no cost to society. (R13)	T	GN B C
Land use and land cover change				Afforestation, reforestation, improved forest, cropland and rangeland management, and agroforestry provide opportunities to increase carbon uptake, and slowing deforestation reduces emissions. (R13)	T	GN GL B NGO C
Market mechanisms and incentives				The Kyoto Protocol mechanisms, in combination with national and regional ones, can reduce the costs of mitigation for developed countries. In addition, countries can reduce net costs of emissions abatement by taxing emissions (or auctioning permits) and using the revenues to cut distortion taxes on labor and capital. In the near term, project-based trading can facilitate the transfer of climate-friendly technologies to developing countries. (R13)	E	GI GN B
Adaptation				Some climate change is inevitable and ecosystems and human societies will need to adapt to new conditions. Human populations will face the risk of damage from climate change, some of which may be countered with current coping systems; others may need radically new behaviors. Climate change needs to be factored into current development plans. (R13)	I	GN GL NGO C R

## 25 **Millennium Ecosystem Assessment Board of Review Editors**

### 26 **Co-Chairs**

27 José Sarukhán, Universidad Nacional Autónoma de México, Mexico  
28 Anne Whyte, Mestor Associates Ltd., Canada  
29

### 30 **Board Members**

31 Antonio Alonso Concheiro, Analítica Consultores Asociados, Mexico  
32 Joseph Baker, Queensland Department of Primary Industries and Fisheries, Australia  
33 Arsenio Balisacan, Southeast Asian Regional Center for Graduate Study and Research in  
34 Agriculture, Philippines  
35 Fikret Berkes, University of Manitoba, Canada  
36 Julia Carabias, Universidad Nacional Autónoma de México, Mexico  
37 Gerardo Ceballos, Universidad Nacional Autónoma de México, Mexico  
38 Robert Costanza, University of Vermont, United States  
39 Marian S. de los Angeles, The World Bank, United States  
40 Navroz K. Dubash, National Institute of Public Finance and Policy, India  
41 Faye Duchin, Rensselaer Polytechnic Institute, United States  
42 Jeremy S. Eades, Ritsumeikan Asia Pacific University, Japan  
43 Mohamed A. El-Kassas, University of Cairo, Egypt  
44 Paul R. Epstein, Harvard Medical School, United States  
45 Jorge D. Etchevers, Colegio de Postgraduados, Mexico  
46 Exequiel Ezcurra, Instituto Nacional de Ecología, Mexico  
47 Naser I. Faruqi, Environment Canada, Canada  
48 Christopher Field, Carnegie Institute of Washington, United States  
49 Blair Fitzharris, University of Otago, New Zealand  
50 Gilberto Gallopin, Economic Commission for Latin America and Caribbean, Chile  
51 Peter Gardiner, Independent consultant, Malaysia  
52 Mario Giampietro, Istituto Nazionale di Ricerca per gli Alimenti e la Nutrizione, Italy  
53 Andrew Githeko, Kenya Medical Research Institute, Kenya  
54 Allen Hammond, World Resources Institute, United States  
55

- 1 Marc J. Hershman, University of Washington, United States
- 2 Brian John Huntley, National Botanical Institute, South Africa
- 3 Pedro R. Jacobi, Universidade de São Paulo, Brazil
- 4 Pavel Kabat, Wageningen University, Netherlands
- 5 Roger Kaspersen, Clark University, United States
- 6 Robert W. Kates, Independent Scholar, United States
- 7 Tony La Viña, World Resources Institute, Philippines
- 8 Sarah Laird, Independent Scholar, United States
- 9 Sandra Lavorel, Université Joseph Fourier, France
- 10 Neil A. Leary, International Global Change System for Analysis Research and Training
- 11 Secretariat, United States
- 12 Kai Lee, Williams College, United States
- 13 Ariel E. Lugo, United States Department of Agriculture - Forest Service, Puerto Rico
- 14 Yuzuru Matsuoka, Kyoto University, Japan

- 41 Kedar Lal Shrestha, Institute for Development and Innovation, Nepal
- 42 Bach Tan Sinh, National Institute for Science and Technology Policy and Strategy Studies,
- 43 Vietnam
- 44 Otton Solis, Costa Rica
- 45 Avelino Suárez Rodríguez, Cuban Environmental Agency, Cuba
- 46 Jatna Supriatna, University of Indonesia, Indonesia
- 47 DanLing Tang, Fudan University, China
- 48 Holm Tiessen, Goettingen University, Germany
- 49 Hebe M.C. Vessuri, Venezuelan Institute of Scientific Research, Venezuela
- 50 Angela de L. Rebello Wagener, Pontificia Universidade Católica do Rio de Janeiro, Brazil
- 51 Wang Rusong, Chinese Academy of Sciences, China
- 52 Wolfgang Weimer-Jehle, University of Stuttgart, Germany
- 53 Philip Weinstein, University of Western Australia, Australia
- 54 Thomas J. Wilbanks, Oak Ridge National Laboratory, United States
- 55 Xu Jianchu, International Center for Integrated Mountain Development, Nepal

- 1 Michael Young, Commonwealth Scientific and Industrial Research Organization, Australia
- 2 Linxiu Zhang, Chinese Academy of Sciences, China

## Appendix D. Abbreviations and Acronyms

### Abbreviations and Acronyms

BSE – bovine spongiform encephalopathy  
CBD – Convention on Biological Diversity  
DALY – disability-adjusted life year  
FAO – Food and Agriculture Organization (United Nations)  
GDP – gross domestic product  
GHS – greenhouse gases  
GNP – gross national product  
IPCC – Intergovernmental Panel on Climate Change  
IUCN – World Conservation Union  
IVM – integrated vector management  
MA – Millennium Ecosystem Assessment  
MEA – multilateral environmental agreement  
MDG – Millennium Development Goal  
NGO – nongovernmental organization  
NPP – net primary productivity  
NTFP – non-timber forest product  
OECD – Organisation for Economic Co-operation and Development  
PA – protected area  
RBO – river basin organization  
SARS – severe acute respiratory syndrome  
UNCCD – United Nations Convention to Combat Desertification  
UNEP – United Nations Environment Programme  
UNFCCC – United Nations Framework Convention on Climate Change  
WWF – World Wide Fund for Nature

### Chemical Symbols, Compounds, Units of Measurement

CH<sub>4</sub> – methane  
CO – carbon monoxide  
CO<sub>2</sub> – carbon dioxide  
GtC-eq – gigatons of carbon equivalent  
N – nitrogen  
N<sub>2</sub>O – nitrous oxide  
NO<sub>x</sub> – nitrogen oxides  
ppmv – parts per million by volume  
SO<sub>2</sub> – sulfur dioxide  
teragram – 10<sup>12</sup> grams

## Appendix E. Assessment Report Tables of Contents

Note that text references to CF, CWG, SWG, RWG, or SGWG refer to the entire working group report.

### Conceptual Framework – *Ecosystems and Human Well-being: A Framework for Assessment*

- CF.1 Introduction and Conceptual Framework
- CF.2 Ecosystems and Their Services
- CF.3 Ecosystems and Human Well-being
- CF.4 Drivers of Change in Ecosystems and Their Services
- CF.5 Dealing with Scale
- CF.6 Concepts of Ecosystem Value and Valuation Approaches
- CF.7 Analytical Approaches
- CF.8 Strategic Interventions, Response Options, and Decision-making

### Condition and Trends Working Group Report

- SDM Summary
- C.01 MA Conceptual Framework
- C.02 Analytical Approaches for Assessing Ecosystems and Human Well-being
- C.03 Drivers of Change (*note: this is a synopsis of Scenarios Chapter 7*)
- C.04 Biodiversity
- C.05 Ecosystem Change and Human Well-being
- C.06 Vulnerable People and Places
- C.07 Freshwater Ecosystem Services
- C.08 Food Ecosystem Services
- C.09 Timber, Fuel, and Fiber
- C.10 Novel Products and Industries from Biodiversity
- C.11 Biological Regulation of Ecosystem Services
- C.12 Nutrient Cycling
- C.13 Air Quality and Climate
- C.14 Human Infectious Disease Agents
- C.15 Waste Processing and Detoxification
- C.16 Regulation of Natural Hazards
- C.17 Cultural and Amenity Services
- C.18 Marine Systems
- C.19 Coastal Systems
- C.20 Inland Water Systems
- C.21 Forest Systems
- C.22 Dryland Systems
- C.23 Island Systems
- C.24 Mountain Systems
- C.25 Polar Systems
- C.26 Cultivated Systems
- C.27 Urban Systems
- C.28 Synthesis

### Scenarios Working Group Report

- SDM Summary
- S.01 MA Conceptual Framework
- S.02 Global Scenarios in Historic Perspective
- S.03 Why is it Important to Include Ecology in Global Scenarios?
- S.04 State of Art in Describing Future Changes in Ecosystem Services
- S.05 Scenarios for Ecosystem Services: Rationale and Overview
- S.06 Methodology for Developing the MA Scenarios
- S.07 Drivers of Change in Ecosystem Conditions and Services
- S.08 Four Scenarios
- S.09 Changes in Ecosystem Services and Their Drivers across the Scenarios
- S.10 Biodiversity across Scenarios
- S.11 Human Well-being across Scenarios

- S.12 Synergies and Trade-offs Among Ecosystem Services
- S.13 Lessons Learned for Assessments
- S.14 Synthesis: Policy Implications

### **Responses Working Group Report**

- SDM Summary
- R.01 MA Conceptual Framework
- R.02 Typology of Responses
- R.03 Assessing Responses
- R.04 Recognizing Uncertainties in Evaluating Responses
- R.05 Biodiversity
- R.06 Food and Cultivated Ecosystems
- R.07 Water
- R.08 Wood, Fuelwood, and Non-Wood Forest Products
- R.09 Nutrient Management
- R.10 Waste Management, Processing, and Detoxification
- R.11 Flood and Storm Control
- R.12 Ecosystems and Vector-borne Disease Control
- R.13 Responses to Climate Change
- R.14 Cultural Services
- R.15 Integrated Responses
- R.16 Consequences and Options for Human Health
- R.17 Consequences of Responses for Poverty Reduction, Ecosystem Services, and Human Well-being
- R.18 Choosing Responses
- R.19 Implications for Achieving the MDGs

### **Sub-Global Working Group Report**

- SDM Summary
- SG.01 MA Conceptual Framework
- SG.02 Overview
- SG.03 Linking Ecosystem Services and Human Well-being
- SG.04 Multi-Scale Approach
- SG.05 Knowledge Systems
- SG.06 Assessment Process
- SG.07 Drivers of Ecosystem Change
- SG.08 Condition and Trends
- SG.09 Responses
- SG.10 Scenarios
- SG.11 Community Assessments
- SG.12 Synthesis
